Deviations from normal balance may be negative or positive. In the former salt depletion arises from abnormal losses of salt in alimentary secretions, sweat, or urine (Addison's disease). Half, or even slightly more, of the total body salt may be lost. The salt of extracellular fluid may fall to one-third or even one-quarter of normal, this statement is not based on direct measurement but on deductions from data regarding the amount of salt needed to restore normal balance (Marsh, 1937, Bartlett *et al*, 1938, Sanchez-Vegas and Collins, 1946, Marriott, 1946). Such depletion in a 70-kg man represents 3 oz (85 g) of salt, or the amount in 10 litres (18 pints) of isotonic saline. The causation and effects of salt depletion will later be more fully discussed.

Some consideration of positive deviation from balance (salt retention) is necessary because it has a bearing on the treatment of salt depletion. It occurs from excessive administration of saline or from inefficient renal excretion of salt. It also arises, still more commonly, when imbalance of hydrostatic and osmotic pressures causes a relative shift of fluid from the vascular to the interstitial compartment. This may be due to rise of intravascular hydrostatic pressure, as in congestive cardiac failure or venous obstruction, or to decrease of plasma protein osmotic pressure from hypoproteinaemia (albumin less than 3 g per 100 ml; Bruckman and Peters, 1930, Weech *et al*, 1931, 1933, Humsforth, 1946) due to starvation, insufficient absorption, inadequate hepatic synthesis, or abnormal protein loss in urine or exudate. Frequently an important part is played by increased capillary permeability, permitting escape of protein, due to mechanical, thermal, anoxic, or toxic damage (Landis, 1937). Whenever salt is retained water is also retained to the extent of 1 litre for every 6 or 7 g of sodium chloride (De Wesselow, 1924). The body tolerates a gross excess of extracellular fluid far better than it does any change in its salt concentration (Stewart and Rourke, 1942). In severe generalized oedema there may be more than 100 lb (45.3 kg) of additional extracellular fluid, and the extra salt within the body may cause the body's total to be three times as much as normal. For example, a man normally weighing 70 kg may contain over 1 lb (453.6 g) of salt instead of 6 oz (170 g).

In oedematous states the restriction of water intake, so long practised, tends merely to cause the extracellular fluid to become hypertonic because the kidneys are provided with insufficient water to excrete the excess of salt. In consequence water tends to be sucked out of the cells. Hence the patient, though massively oedematous, may actually suffer from cellular dehydration (Schemm, 1942, 1944) and complain of thirst and dry mouth, which are symptomatic of cellular desiccation (Dill, 1938). Every clinician of experience has seen such cases in which the water in the great pool of tissue fluid is not available to the kidneys and thus a policy of water restriction has

little influence on the oedema but causes oliguria and may produce uraemia. Such patients are better regarded as brine-loaded (Schemm, 1942) rather than water-loaded. The really important consideration in their treatment, apart from rectification of the fundamental cause of the oedema, is restriction of daily intake of sodium chloride to not more than 15 g. The kidneys will not, save in exceptional circumstances, retain water in the absence of salt, for they obey their fundamental law, as chief regulators of the internal environment, that extracellular isotonicity is the prime consideration. For example, it is very difficult under experimental conditions to produce oedema from hypoproteinaemia if salt is restricted (Kerlhof, 1938). In patients suffering from cardiac failure, and on a regimen of severe salt restriction, daily water intake may exceed 6 litres (Leevy *et al*, 1946) and even reach 10 litres (Schemm 1942) without increase of the oedema. Actually in such cases it would seem that the right course is neither to restrict nor to force water intake but to allow the patient whatever water he desires (Leevy *et al*, 1946).

Salt in Alimentary Secretions and Sweat

The salt content, with the relative sodium and chlorine ratios, in the alimentary secretions and sweat is shown in Fig. 7 (after Gamble, 1923, 1942, and McCance, 1936).

FIG. 7—Salt content of alimentary secretions and sweat with relative sodium and chloride ratios.

The great predominance of these ions should be noted. The quantity of the various secretions daily secreted into and reabsorbed from the alimentary tract is shown in Table III (Rowntree 1922, Gamble, 1942; Abbott, 1946). So far as sweat is concerned, it needs to be appreciated that there are two kinds—insensible and sensible. Insensible sweat (Sanctorius 1614, Newburgh and Johnston, 1942) vaporizes continuously and invisibly from the body even under cold atmospheric conditions. Its average amount is about 600 ml. daily. Its sodium content is said to be negligible and it may be regarded as practically distilled water (Nadal, Pedersen, and Maddock, 1941). Sensible sweat is secreted when the body becomes heated. In the tropics its volume may reach 3 gallons (13.5 litres) a day.

TABLE III—The Alimentary Secretions

	ml.
Saliva	1,500
Gastric juice	2,500
Pancreatic juice	700
Bile	500
Intestinal juice	3,000
Total	8,200*

* Amount of 2 pints with 2 oz. of sodium chloride.

(Harris 1912). It is virtually isotonic saline, since sodium and chloride are its main constituents. The concentration of sodium chloride varies from 1 to 5 g. per litre in different individuals (Moss 1923, Kuro 1934, McCance, 1936, Dill 1938, Madel, Viceroy, and Hudson 1944). The average concentration for Europeans is usually around 2.5 to 3.0 g. per litre or 1.3 to 1.4 oz. per gallon.

Under normal conditions in Britain nearly all salt excretion is by way of the urine and individuals lose only a very small proportion of their daily salt intake from the sweat. This is true even from the tropics.

Physiological Functions of Salt

As already shown, sodium and chlorine are the chief components of extracellular fluid (tissue fluid + plasma), the alimentary secretions, and sweat. In the extracellular fluid the main function, already discussed, of these ions appears to be to supply osmotic pressure so that isotonicity with intracellular fluid is preserved. Another function is that sodium and chlorine play principal parts in the acid-base balance of extracellular fluid. As is well known, the general tissue cells require an environment of constant slight alkalinity, and the various acid-base regulating mechanisms work to preserve it. In Figs 2 and 7 basic and acid radicals occupy respectively the left and right columns of each diagram. Reference to Fig. 2 shows that in extracellular fluid more than 90% of the total base is represented by sodium and more than 70% of the total acid by chlorine.

In the alimentary secretions the chief functions of sodium and chlorine again appear to be concerned with osmotic pressure and acid-base adjustment. As regards osmotic pressure, the cells lining the alimentary tract, particularly in its upper part, are adapted to withstand non-isotonic fluids. Nevertheless isotonicity appears to be an important consideration, since with the exception of saliva, these secretions are all approximately isotonic with tissue fluid (see column heights in Fig. 7). As regards acid-base adjustment, the various digestive enzymes need widely differing conditions of acidity and alkalinity. In consequence sodium and chlorine are secreted in the varied ratios shown in Fig. 7.

In sensible sweat sodium and chlorine seem almost accidental constituents and not to have important functions. The reason for this statement is that there is such a wide individual difference in the salt concentration of the sweat of different persons that it seems hard to believe that any particular concentration matters. In tropical countries the salt content of the sweat of natives or long-time residents appears to be much lower than that of new arrivals (Dill, 1938, Lee *et al*, 1941).

Renal Regulation of Extracellular Sodium and Chlorine

As Gamble (1937) has said "The kidney is very inadequately described as an organ of excretion. Were removal of waste products its only function, a much simpler mechanism would suffice. Its complexity of design and intricacy of function are required for the construction and accurate defence of extracellular fluid on the chemical constancy of which depends the successful operation of intracellular processes. Renal conservation of the constancy of the internal environment is achieved by selective reabsorption of the components of the glomerular filtrate. First in importance among them are water, sodium, and chlorine. In normal adults the maximum attainable urinary concentration of chlorine is about 0.33 N (Davies, Haldane, and Plesent, 1922). Expressed as NaCl this concentration equals approximately 2% of salt in urine. The concentration of chlorine and HCO_3 equals 0.33 N of either or of both together. The maximum for sodium seems to be of the same order or a little higher. The ability of the kidneys to excrete sodium and chlorine, together or separately, has an important bearing on the administration of saline. In adults the renal concentrating power may be damaged in the common conditions mentioned in the section on minimum urine volume, and in these conditions patients may be unable to excrete salt in concentrations exceeding 0.4% (approximately 1/2 isotonic saline). In normal infants the ability to excrete salt is much less than in adults (McCance and Young, 1941, 1942; McCance 1946). This explains why the...

and Young found the sodium and chlorine clearances in full-term babies aged 7-14 days to be about one-fifth of the value they would be likely to acquire in later life. Still lower clearances were found in premature babies (Young, Hallum, and McCance, 1941).

As is now well known, the cortex of the suprarenal glands plays an important part in regard to renal excretion of salt. In experimental adrenalectomy or in Addison's disease there is an excessive excretion of sodium chloride, and in consequence the plasma level falls. Excretion may continue in Addison's disease even when the plasma chloride, expressed as NaCl, is below 500 mg per 100 ml (Anderson and Lyall, 1937). The subject has been reviewed by Loeb (1941), whose own work in this field has been of such importance. Detection of the tendency to excessive salt excretion, under standard conditions of salt restriction, is the basis of the well-known test for Addison's disease which has been devised by Cutler *et al* (1938a, b). There is similarity in failure of hormonal control causing excessive excretion respectively of water and salt in diabetes insipidus and in Addison's disease. However, in the former the body is saved from very serious consequences by the protective mechanism of thirst, while in the latter there is no equivalent salt-craving. In passing it should be observed that in diabetes insipidus there is no increase of salt excretion or fall in plasma chloride level—this was the finding of Blotner (1941) in 22 cases of that disease.

(Part II will be published in the next issue)

THERAPEUTIC POSSIBILITIES OF RADIO-PHOSPHORUS

BY

J S MITCHELL, M.B., Ph.D

Radio-phosphorus (P^{32}) has been used since 1936 in the treatment of patients with chronic myeloid and lymphatic leukaemia, polycythaemia vera, lymphosarcoma, and various related diseases. Most of this work has been done in the U.S.A. Important summaries of the American results have been given by Low-Beer, Lawrence, and Stone (1942), Kenney (1942), and Reinhard, Moore, Bierbaum, Moore, and Kamen (1946). Of great interest is a paper from Stockholm by Lindgren (1944).

Clinical trials of the therapeutic possibilities of radio-phosphorus have not yet been carried out in Great Britain although tracer studies with P^{32} made by cyclotrons are in progress. However, it now seems reasonably certain that within the next year we shall be fortunate enough to obtain adequate and regular supplies of P^{32} made by means of a "pile". The isotope P^{32} is produced in the pile from ordinary phosphorus (P^{31}) by slow neutron capture and is used in the form of isotonic Na_2HPO_4 solution (15 mg per ml), with initial radioactivity of about 300 microcuries per ml. The pile can produce a specific gravity of one-third curie of P^{32} per g of phosphorus. The P^{32} given therapeutically should be accompanied by the smallest possible amount of P^{31} .

Dosage

The radioactivity of the phosphate solutions used can be determined by means of a Laursen electroscope calibrated with a uranium standard, but for clinical investigations a Geiger counter is essential. It appears most satisfactory to give the radioactive phosphate solution intravenously, usually in unit doses of the order of 0.5-2 millicuries. However, oral administration is possible, and it is stated

that "it is the practice of most workers who give P^{32} orally to assume that 75% of any given dose is absorbed."

The physical properties of P^{32} are well known. This isotope has a half-life of 14.3 days and emits only beta particles. The maximum energy of the beta particles is 1.71 mev, the mean energy of the beta particles is of great importance in clinical applications and has the approximate value of 0.70 mev.

Although as yet most of the clinical dosage of P^{32} has been necessarily empirical, it seems highly desirable to correlate the dose of radioactive isotopes with the roentgen unit. An important paper on this subject was published by Marinelli (1942). It can be shown that 1 microcurie of P^{32} per g of tissue delivers 43 r per day, 1 g roentgen corresponds to 1.13 microcuries destroyed per kilogram of tissue, and if 1 millicurie is retained for 24 hours by a patient weighing 70 kg, approximately 0.6 roentgen equivalents of whole body radiation are delivered. In radioactive isotope therapy it is useful to measure the differential absorption ratio for the isotope, which may be defined as the ratio of the concentration of the radioactive material in a particular tissue to the mean concentration in the body as a whole. The possibility of delivering useful doses of radiation in any particular case may be determined by measuring the differential absorption ratio by means of tracer studies (Kenney, Marinelli, and Woodard, 1941). In this way it was found impossible to deliver therapeutically useful doses of beta radiation from P^{32} to the primary tumour or metastases in cases of carcinoma of the breast and of osteogenic sarcoma. The present tendency in all diseases except polycythaemia vera appears to be to follow the "fractional method" of dosage of P^{32} outlined by Low-Beer, Lawrence, and Stone (1942). It seems that one can treat a typical case of chronic myeloid leukaemia with an initial dose of perhaps 1 millicurie of P^{32} , followed by five doses of 0.5 millicurie at three- to four-day intervals, and then doses of 0.5 millicurie weekly until the total white cell count has fallen to about 30,000 per cmm. Then one or two fractions may be given subsequently at longer intervals. The whole clinical and haematological picture must obviously be taken into account. It seems likely that the above unit doses can be safely doubled in some cases, with reduction of the over-all time of treatment. The average treatment for the 39 cases of chronic myeloid leukaemia reported by Reinhard *et al* (1946) corresponds to 11.8 millicuries of P^{32} administered in 78 days. In the treatment of polycythaemia vera it is recommended that the initial dose is 3.5 to 4 millicuries of P^{32} . This may suffice, but in some cases it is necessary, after waiting three months, to give a second dose of 1 to 3 millicuries; ancillary venesection is often advisable.

Therapeutic Value

It is not yet possible to assess with confidence the therapeutic value of radio-phosphorus, but it is evident that the earlier optimism is not yet justified. The conclusion reached by Reinhard *et al* (1946) may be summarized as follows:

- 1 Radio-phosphorus is probably the best therapeutic agent available at the present time for polycythaemia vera.
- 2 The results of treatment by radio-phosphorus of patients with chronic myeloid leukaemia are probably comparable with those of the usual x-ray therapy but are not substantially better. With P^{32} , freedom from radiation sickness is a practical advantage which patients who have had previous x-ray therapy appreciate. Great care appears to be necessary in treatment with P^{32} to avoid serious damage to the bone marrow.
- 3 "In the treatment of chronic lymphatic leukaemia radio-phosphorus is probably as satisfactory as, but not better than, roentgen radiation."

4 Radio phosphorus is of no value in the treatment of acute leukaemias or of monocytic leukaemia

5 Hodgkin's disease lymphosarcoma reticulum cell sarcoma and multiple myeloma do not respond as favourably as P³² as they do to x radiation

6 The limited evidence available suggests that radio phosphorus is not likely to prove to be a satisfactory agent for the treatment of carcinoma of the breast malignant melanoma lympho epithelioma Ewing's tumour or mycosis fungoides

However, the work of Kenney (1942) suggests that further clinical trials of radio phosphorus in lymphosarcoma are desirable

It seems doubtful whether radio-phosphorus, in the form of inorganic phosphate, will stand the test of time even in the treatment of chronic myeloid leukaemia. In his report to the United Nations Atomic Energy Commission on Sept. 23, 1946, Dr C P Rhoads, the Director of the Memorial Hospital, New York, discussed the treatment of chronic myeloid leukaemia and concluded that 'a tendency in most institutions is to discard the use of radio-phosphorus and to stick to conventional x ray as being somewhat safer and more predictable in its results and attended by less hazards to the patient even though it does cause some illness in the course of treatment'

In conclusion, one can quote again from Dr Rhoads report. To have expected inorganic elements to be picked up so selectively and concentrated so adequately by cancer tissue as compared to normal tissue was a very optimistic hope. I am not surprised that we are somewhat disappointed, but we have a vast field before us. We are beginning to study the selective pick-up by cancer of a vast variety of organic compounds which can be synthesized in the laboratories of organic chemistry to contain radioactive isotopes of a variety of elements. I am very hopeful.

A final aspect of the therapeutic application of radio-phosphorus is the possibility of development of beta-ray applicators using P³² perhaps incorporated in plastics. A report on human skin reactions produced by the external use of radio phosphorus has been published recently by Low Beer (1946). The estimated number of roentgen equivalents dissipated in the first millimetre of tissue is 4.3 per hour per microcurie per square centimetre area. The maximum range of the beta-particles from P³² is approximately 8 mm in water or unit-density tissue. It is stated that half-value layer measurements have shown that about 48% of the radiation is absorbed in the first millimetre of tissue. The results of these studies suggest that the use of radioactive phosphorus in the local treatment of certain superficial skin diseases is reasonable.

PINK DISEASE: A REVIEW OF 65 CASES

BY

T N FISHER, MB, MRCP, DPH

Physician Royal Manchester Children's Hospital Physician for Children Manchester Northern Hospital Consulting Physician for Children Warrington Infirmary

Pink disease sprang into prominence in medical literature in the early years of the century and seems to have established itself in this country as a not very common but nevertheless, regularly recurring member of the group of diseases incident to infancy and early childhood. I have reviewed the case histories of patients who attended my out-patient clinic at the Royal Manchester Children's Hospital during the 14 years from 1932 to 1945 to see if any further light can be thrown on the nature of this still somewhat puzzling ailment. During this period 65 infants and young children—27 males and 38 females—suffering from the disease came under my observation. I followed the progress of 48 of these from the time of their first attendance to the end of their illness. The remaining 17 I saw on only one or two occasions, but I ascertained the subsequent progress of 14, the other three I was unable to trace. Of the 62 children whose subsequent progress is known 53 made a complete recovery and 9 died.

Incidence of the Disease

Year	1932	1933	1934	1935	1936	1937	1938	1939	1940	1941	1942	1943	1944	1945
No. of cases	3	4	5	4	1	5	3	7	6	6	7	2	5	7

There was a fairly even distribution over the whole period. The drop in numbers in 1936 and 1943 can have no significance where such small numbers are concerned unless other observers have noted a similar feature.

Month of Onset of the Disease

Month	Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
No. of cases	8	4	6	5	4	6	5	4	7	6	2	5

These figures embrace the whole period and show that there was no demonstrable variation in seasonal incidence. The impression that it is commoner during the winter months can, I think, be explained by the greater severity of the disease due to intercurrent infection, during that period of the year.

Age of Onset

Age in Months	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	25	38	50
No. of cases	1	4	3	6	6	9	2	8	7	0	4	2	1	1	2	2	1	1	3	1	1

The figures show a rapid increase from the age of 4 months (the earliest age at which the disease occurred) to the end of the first year, and thereafter a sharp decline. The two children who succumbed to the disease in their fourth and fifth years were quite outside the usual age period in this series. A calculation of the average age of onset in each year throughout the period shows no significant trend in the behaviour of the disease towards an earlier or later susceptible age of choice.

Average Duration for Each Year

Year	1932	1933	1934	1935	1936	1937	1938	1939	1940	1941	1942	1943	1944	1945
Duration in months	3.5	3.3	3.7	3.8	—	4.1	3.0	3.7	4.7	3.0	4.6	—	5.3	3.9

In 1936 one case was seen (duration 3.5 months). Two cases were seen in 1943 but the duration of the disease could not be determined for one of the children.

The average duration in 46 infants recovering from the disease was four months. The shortest was six weeks, the longest nine months. Here, again, there is no demonstrable change in behaviour, and little to support the impression I had formed that the disease tends to strike at an earlier age and to run a more protracted but milder course in recent years.

Age of onset did not have any significant influence on the duration of the disease, though it may be remarked that all infants whose symptoms persisted for more than five months had the ailment before the end of their first year. The eighth month seems to be the most common, and from the point of view of duration and morbidity the most unfavourable, age at which to contract the disease. The patients came indiscriminately from the whole area (predominantly industrial) served by the hospital, and no predilection for any particular region or district was detected. Nor could social or financial status be shown to have any obvious influence. No evidence remotely suggesting transmission of the disease from one child to another came to light, and the theory of dietetic deficiency or lack of balance received no support from a study of the case histories.

Symptoms

The disease develops insidiously and is usually well established when the infant is brought to hospital. No first-hand observations can therefore be made concerning the onset, beyond noting that there is seldom any history of previous ill-health or serious dietetic mismanagement. A study of the case notes and of the clinical course of the disease as it unfolds itself readily suggests a natural division of the symptoms into two groups: the basic symptoms, constant and persisting throughout the duration of the disease, and the inconstant and variable cutaneous manifestations. The troublesome and dangerous intercurrent infections to which infants suffering from this disease are particularly susceptible are always ready to take advantage of any carelessness in management. There are three basic symptoms: a profound change in temperament, muscular hypotonia, and tachycardia.

The hitherto thriving infant loses his normal contented disposition and gradually comes to present a picture of unhappiness far exceeding in intensity and duration the intermittent fractiousness of teething, to which process the symptoms of the disease are at first too readily ascribed. The unhappiness increases until, finally, he exhibits a continuous, miserable, peevish resentfulness or an active, militant fury against all the agencies of the external world and particularly its immediate representatives, his mother or the examining physician. Muscular hypotonia may be extreme. The art of walking if already attained is lost. The infant slumps spinelessly in his mother's arms, with his face buried in her shoulder. The hypotonia is most characteristically seen in the thigh muscles, which lie flaccidly on either side of the femur and may, in severe cases, have almost a semi-fluid consistency on palpation. A persistently rapid pulse rate of between 144 and 168, rising to 192 under the provocation of examination or other interference, completes the basic pattern of the disease.

Superimposed on this sustained picture of infantile distress the cutaneous symptoms vary considerably in their time of onset, intensity, and duration. They include the vasomotor phenomena of the extremities: the rash, excessive perspiration and the special manifestations affecting the buccal and conjunctival mucous membranes. The puffy, pink or bluish red, cold clammy hands and feet and the sudaminal eruption on the trunk and limbs, criss-crossed by excoriation from the constant scratching, are the two most regularly appearing features. The rash may be transient and of only a few days' duration or may persist for

several weeks. In 12 of 32 infants whose history could be regarded as reliable the rash and swollen extremities were said to have been present from the onset. In the remaining 20 they appeared at varying periods from two to eight weeks after the onset. Profuse sweating is a commonly associated feature which exacerbates the rash and helps to give the moist, cold, flabby, almost reptilian feel to the infant's skin. Desquamation appears from two to three weeks later, and reflects, in the extent and depth of the exfoliation, the intensity of the rash.

Buccal irritation, which is often rather to be inferred from the infant's facial expression of profound disgust or distaste and his obstinate refusal of food and drink than from any obvious lesion of the mucous membrane, may be the cause of most intractable and distressing anorexia, which is overcome only by the exercise of much patient perseverance on the part of the child's attendants. Conjunctival irritation, resulting in photophobia but with no visible evidence of conjunctival inflammation, is the most inconstant of the cutaneous symptoms. It may be entirely absent barely perceptible, or quite a leading feature of the disease. In two infants it was a most troublesome symptom, persisting for some weeks after the other signs and symptoms had subsided, but finally disappearing without any evidence of organic ocular disease.

In only one case the child of 4 years, was there an opportunity of getting any subjective account of the symptoms. He complained that his back was always itching and his hands and feet were smarting; he also complained of vague pains in his arms and legs. The majority can give no verbal interpretation of their feelings, but contemplation of the intense erythema and swelling of the extremities to be seen in many sufferers and the exercise of a little imagination should provide a completely adequate explanation for the extreme state of misery to which they are reduced.

The intercurrent infections to which infants suffering from this disease are particularly prone comprise low-grade superficial skin infections, deeper ulcerations in the flexures of the hands and feet when desquamation takes the severe exfoliative form, ulcerative stomatitis, which in two infants culminated in sloughing of the gums, shedding of teeth, and septic bronchopneumonia, and respiratory infections, always badly tolerated owing to the hypotonic condition of the thoracic musculature.

Deaths

There were nine deaths in this series: one infant collapsed quite suddenly in hospital at the height of the disease (1935), one died from the effects of a severe skin infection and widespread furunculosis (1940), two died from septic bronchopneumonia secondary to ulcerative stomatitis (1939, 1940) and three died from acute respiratory infections (1933, 1937, 1938). The exact cause of death in two infants could not be ascertained. Post-mortem examinations performed on two of these infants did not throw any light on the pathology of the disease. This inordinately high death rate is almost entirely attributable to intercurrent infection and underlines the vast importance of most careful precautions against the incidence of these dangerous complications.

Treatment

The precise cause of the disease is as yet unknown and treatment has been symptomatic with special emphasis on prevention of secondary infections. It is generally agreed that home nursing is the method of choice. The enhanced dangers of infection in hospital (unless strict cubicle nursing is feasible) the impossibility at present of nurses devoting the necessary time and attention to feeding and maintenance, and the increase in misery and impotent fury, and

the consequent increase in tachycardia, brought about by separation from familiar surroundings and perhaps frequent changes of attendants all weigh heavily in favour of nursing the infant at home unless circumstances make this quite impossible. However exacting the task the mother should be persuaded to make the extra effort. It should be explained to her that in no disease is patient devotion to the interests of the child better rewarded in the end.

Intensive parenteral vitamin or liver therapy was not employed in this series. A high vitamin intake has been advised as a measure of protection against superimposed infection rather than from a predilection for any particular theory of causation. The main principles in management are scrupulous attention to bodily hygiene, particularly when desquamation is in process, most careful segregation from any human source of nasopharyngeal or respiratory infection, and immense patience in feeding—all food should be boiled or cooked and served as cold as possible (sometimes the only way food or fluid will be taken at all), and food should not be forced into the mouth because of the danger of injury to the buccal mucous membrane and subsequent stomatitis.

The judicious use of sedatives and the local application of such soothing and cooling preparations or physiotherapeutic measures as seem to bring the greatest relief to the patient without causing maceration of the tissues must be a matter of individual experiment and ingenuity. There is no single royal road to success in easing the intense discomfort which is often the most harrowing feature of the disease.

Summary

A review of 65 cases of pink disease is presented. The progress in 62 was ascertained. 53 completely recovered and nine were fatal.

The incidence, age of onset and duration of the disease are given.

The symptoms are divided into two groups and these are discussed.

Treatment and the prevention of secondary infections are dealt with and the advantages of home nursing are emphasized.

PELLAGROUS ENCEPHALOPATHY

BY

PHILIP R. GRAVES, MBE, MD, MRCP

Late Medical Specialist R.A.M.C. Hon. Assistant Physician
Chester Royal Infirmary

The following account deals with a deficiency syndrome which occurred among prisoners of war in Singapore. As the title indicates, the clinical manifestations suggested a brain lesion; the only pathological support for this contention was the naked eye appearances of the brain and spinal cord at the necropsies on the fatal cases. No histological examination was possible. The syndrome occurred in the form of a comparatively small outbreak after large epidemics of vitamin B₁ deficiency resulting in neuritic and oedematous beriberi and Wernicke's encephalopathy, and later epidemics of B₁-complex deficiencies giving rise to angular stomatitis, glossitis, scrotal dermatitis, pellagra dermal lesions, retrobulbar neuritis, and the painful feet syndrome. So far as I am aware, no such outbreak as this has been previously reported.

This neurological disorder was remarkable for the appearance of spastic paraplegia and for the sake of description and recognition among the medical officers of the camp it was termed the "spastic syndrome". The initial illness varied in severity from a state of deep coma to some effects so slight as to be recognized only by the existence of extensor plantar responses. The residual symptoms similarly varied from a persistent spastic paraplegia so severe as to disable walking to a recovery so complete that no signs remained.

With the assistance of the ward medical officers who had charge of them I was able to keep a close watch on the first

group of cases to be admitted to hospital between August and November 1942. Other cases arising later I saw at less frequent intervals but the total number under close personal observation was 29. In January 1944 I extracted from the hospital records data from 34 undoubted cases of this syndrome which were not included in my previous number. Under the prevailing circumstances it was impossible to see or arrange to see every case suspected of the condition so that this report of 63 cases fails to embrace the total number figuring in the official camp statistics.

In this series there were 6 deaths. Four of these patients after an insidious onset deteriorated rapidly and died within 3, 8, 17 and 18 days of admission to hospital. Necropses were performed by Capt. Lennox, R.A.M.C. and the naked-eye findings are included in the case reports. One patient died of pulmonary tuberculosis and no necropsy was carried out. The sixth died a year after onset with progressive mental deterioration; no changes were found in his brain comparable with those in the other cases.

The records I managed to keep with me and finally brought home in October 1945 were of the briefest. As my notes on various diseases grew in number, so the records needed to be condensed still further to reduce their bulk for there was the ever present possibility of confiscation.

Fatal Cases

Case I

This patient, who was admitted on Aug. 31, 1942, had complained for one week of double vision, burning pains in the feet and left hand, general weakness and difficulty in chewing his food. Mentally he was retarded, and was easily moved to laughter by unamusing remarks. There was general weakness of his limbs of moderate degree, most marked in the grip of the left hand. No changes in sensation were observed.

When I next saw him eight days later, generalized rigidity of his limbs had developed and he was unable to sit up. His tendon reflexes were exaggerated and there was ill-sustained clonus at both ankles. The abdominal reflexes were weak, and the plantar reflex was extensor on the left side. He was given marmite 2 oz. (56.7 g.) daily, from then on.

Six days later he became incontinent of urine and during the next few days he was mentally confused. By Sept. 16 his legs had become extended and his arms flexed rigidly across the chest. There was some weakness of the left facial muscles. His temperature rose to 101 F (38.3°C). The following day he became incontinent of stools consisting of blood and mucus, lapsed into unconsciousness and died on Sept. 18.

At necropsy small translucent dots were to be seen scattered about the white matter of the frontal parietal and occipital regions of the cerebral hemispheres. These dots were 2-3 mm in diameter and had the appearance of snow grains in milk. In the colon there was patchy erosion of the crests of the mucous membrane at the distal part of the sigmoid and rectum.

Case II

For a fortnight before his admission on Sept. 4, 1942, this patient had noticed dimness of vision and for a week uneasiness of feet and pain in the neck. On examination there was marked dulling of his mental faculties, with disorientation for time and place. Weakness and rigidity were present in all his limbs with exaggerated tendon reflexes and extensor plantar responses. Other evidence of dietary deficiency was manifested by angular stomatitis, glossitis and scrotal dermatitis. For three days he was given 17 ml (1 anipoule) of nicotinic acid diethylamide intramuscularly and 17 ml by mouth daily. For the next three days 34 ml was given by mouth daily, and subsequently "marmite" 3 oz. (85 g.) daily.

Five days after admission he became incontinent of urine and faeces, he could not speak or swallow, but could understand simple requests and statements. Within the next two days he deteriorated rapidly, his legs became rigidly extended and his arms flexed across his chest. His face was expressionless and practically immobile. The blinking reflex was lost but some vision was present. He moaned continuously so far as could be gathered because of pain in his limbs. This pitiful condition gave place to coma in which he died on Sept. 21.

Changes in the cerebral hemispheres identical with those in Case I were found at necropsy.

Case III

This patient was admitted from another camp on March 22, 1943, in a stuporous condition with a slip attached to his shirt with the words "Fever, Choking feeling and failing vision." He

be roused only to the extent of complaining of headache when asked his symptoms. His temperature was 104° F (40° C). There was an extensive stomatitis with angular fissures, pharyngitis, scrotal dermatitis, and keratitis of the right eye. The latter was occurring in epidemic form and was undoubtedly a deficiency manifestation. His heart sounds were of the tic tac variety, and his blood pressure 120/90. Examination of his nervous system showed that the reaction of the pupils to light was sluggish, reaction to accommodation could not be tested owing to lack of co-operation. There was weakness of the left side of the face and generalized weakness of the limbs, which, so far as could be ascertained, was most marked in the left arm. The abdominal and cremasteric reflexes were absent, as was the right knee jerk. The tendon reflexes of the arms and left patella were normal, but there were bilateral ankle clonus and extensor plantar responses. For treatment he was ordered 'marmite,' 3 oz (85 g) daily, in addition to milk and eggs.

The following day he became incontinent and passed seven semi-solid stools. A lumbar puncture was performed unsuccessfully by two competent medical officers. I could obtain spinal fluid only by aspiration. Examination of the cells and protein showed no deviation from the normal. On March 24 it was noticed that a keratitis had developed in the other cornea, and on the 25th he became deeply comatose and died.

At necropsy similar changes were found in the cerebral hemispheres to those in the two preceding cases. The colon showed extensive mild lesions of bacillary dysentery, with ulcers up to 8 mm in diameter in the upper half of the large bowel.

Case IV

This patient, who was admitted to hospital on March 16 1943, presented what became recognized as the most typical triad—difficulty in walking, dimness of vision, and mental dullness. These symptoms had preceded his admission by two to three weeks. He appeared quite normal mentally, but stated that his memory was poor and his mental faculties slow and dulled. His cranial nerves were normal, and the only objective changes in his nervous system were the absence of abdominal reflexes on the right side and exaggeration of knee and ankle jerks. His diet was supplemented by 'marmite' 3 oz (85 g) daily.

On the 22nd, six days after admission, he became quite rapidly confused. Within a few hours his limbs had taken up the position noticed in the previous cases—legs extended and arms flexed. With this there were associated exaggeration of all tendon reflexes, bilateral ankle clonus and extensor plantar responses, and loss of the abdominal and cremasteric reflexes. Two days later he developed double incontinence, and died, with a temperature rising above 105° F (40.6° C), eight days after admission. A lumbar puncture before death showed fluid under normal pressure and a normal protein and cell content.

At necropsy identical changes were found in the cerebral hemispheres to those in the three previous cases. In the colon there was recent necrosis of the crests of the mucous folds.

Comment

Perusal of these case histories shows (1) a fatal course terminating in from four to five weeks from the onset of the first symptom, (2) clinical evidence of interruption of conduction in the pyramidal system, (3) macroscopical evidence of a pathological process in the white matter of the cerebral hemispheres which would account for most of the physical signs and symptoms including failure of vision. In three out of the four cases there was an ulcerative condition of the colon. Two showed other evidence of deficiency of part of the B₁₂ complex. None of them, to my knowledge had recently suffered from dysentery, malaria or other fever, and repeated blood films failed to reveal parasites. Other negative findings that call for comment are (1) the absence of sensory loss in Cases I, II and IV, from whom some co-operation was possible, (2) no naked-eye changes in the spinal cord, (3) an absence of meningeal reaction, as found by lumbar puncture on two of these cases.

The differentiation from the other neurological disorders—namely Wernicke's encephalopathy and an acute encephalitis—which were occurring fairly often never gave rise to much difficulty as the early symptoms and signs of this syndrome had become well recognized in the less acute cases which had preceded these four fatal ones. It is appreciated that difficulty might arise especially in the case of acute encephalitis, and the history and nature of the early symptoms preceding by some days or weeks the more urgent manifestations of acute disorder of the nervous system are important to the diagnosis of the present syndrome. Wernicke's encephalopathy can be recognized by the symptoms of vomiting and

unsteadiness of the body or eyes and the characteristic nystagmus and ocular palsies. The tendon reflexes are more frequently lost than increased. Only in encephalitis is any deviation from normal expected in the spinal fluid.

The association of this syndrome with other deficiency manifestations and the argument for its recognition as such will be adduced later.

Severe Cases with Ultimate Recovery

Case V

This man was admitted on Sept 7, 1942. He had suffered from the very prevalent complaint of 'pains in the feet' for six weeks. During the preceding three weeks he had developed general weakness, mental depression, anorexia, and failure of vision. On examination he was seen to be suffering from angular stomatitis and glossitis. He was mentally depressed and anxious and apprehensive about himself. His face was without expression and almost immobile. His visual acuity was reduced to an inability to read newspaper print. There was general muscular weakness and rigidity with exaggerated tendon reflexes, ankle clonus, and bilateral extensor plantar responses. The abdominal and cremasteric reflexes remained. No sensory loss, deep or superficial, was found. In addition to a general improvement of his diet he was given 'hepatex,' 4 ml intramuscularly, and 'marmite,' 2 oz (56.7 g) daily.

Two days later he was unable to feed himself and became incontinent of urine. A week later he had developed dysphagia and dysarthria, and his limbs had taken up the characteristic position of flexion of the arms and extension of the legs. He moaned continually and became rather drowsy. His condition at this stage exactly resembled that of Case II during the last ten days of his illness. However, during the next week he began to improve, with a reduction in the rigidity and drowsiness, and in less than a month he was walking about unaided. Within a few days of the commencement of his recovery he developed an inversion of emotional expression and would cry when amused. Although his tendon reflexes remained abnormally brisk until June 1943, his plantar responses had reverted to normal within a fortnight of his first sign of improvement. When last seen, in June, 1943, he was normal in all respects.

Case VI

This patient had noticed double vision and a tight feeling around the head for a fortnight before his admission on Aug 3, 1942. He also described feelings of 'pins and needles' and 'shocks' all over his body. There was general slowing of his mental processes, he was easily amused and was slow in his speech. He exhibited general muscular weakness and rigidity, with exaggeration of all tendon reflexes and knee and ankle clonus. The abdominal reflexes were absent except in the right upper quadrant, as was the right cremasteric reflex. The right plantar response was equivocal, the left flexor. No sensory disturbance was discovered. 'Marmite' 1½ oz (42.5 g) daily, was added to an improved diet.

Four days after admission he had become quite euphoric. The muscular weakness and rigidity had increased and he could not stand up. His physical and mental states deteriorated for the next twelve days, during which time he received intravenous vitamin B₁₂, 2 mg daily. Incontinence of faeces developed. His spinal fluid was examined and found normal. On Aug 20 there were signs of improvement in his general condition, but he was unable to move his ankle or foot joints, and his plantar responses had become extensor. From then onwards his mental condition improved and except for occasional attacks of depression, returned to normal but he was still bedridden in August 1945 with a severe spastic paraplegia.

Case VII

This man, who was admitted on Aug 12, 1942, had been weak and unsteady on his legs for two weeks, had become forgetful and had developed a stutter. His condition at the onset was unique among the cases seen and presented a picture usually the result of congenital cerebral injury or disease. At rest his face presented a vacant expression with open mouth, but this was distorted repeatedly by grimaces and rolling of his eyes and head, accompanied by athetotic movements of the limbs. His gait could only be described as fantastic—a combination of ataxia with the athetotic movements previously mentioned. He was disinterested in his food and was quiet and reserved in his relations with other patients and friends. He was uncommunicative with everyone and very little information could be got from him. Apart from increased activity of his tendon reflexes I could find no other abnormal signs.

Three days later there was no change in his condition, but I found that by taking a forceful line with him I could get him to walk normally. I erred in diagnosing his condition as hysteria and discharging him on the 19th. In mitigation I would like to point out that he was only the third case of this series to be admitted and that he presented a new clinical picture.

A month later he was readmitted with the history that he had been very quiet in his quarters until Sept 12 when for some hours he became violently agitated with much rolling of his head and eyes. He was then quiet again until the 18th when he started screaming and throwing himself about on his bed. He was completely disorientated, and was found to have a temperature of 102° F (38.9° C). Later in the day, after his admission he had an epileptiform seizure with twitching of the right side of the face and right arm, and incontinence. On recovery he behaved in a noisy hysterical manner, but ceased on being reprimanded. For some hours afterwards he exhibited athetotic movements of his limbs and was incapable of speech. On lumbar puncture the fluid was found to be under normal pressure with a normal cell and protein content.

When seen on Sept 26 he had recovered some power of speech using simple words slowly. His limbs were weak and rigid with exaggerated tendon reflexes, ankle clonus and extensor plantar responses were present but the abdominal and cremasteric reflexes were absent. During the next fortnight he became rather emotional and would have fits of crying for no apparent reason. By March 23, 1943, he was able to walk about, but with a fantastic heaving gait as if weights were attached to his feet. All the athetotic movements and rolling of his head and eyes had disappeared. When last seen in August, 1945, he had a spastic paraplegia which just allowed him to get about unaided.

Comment

The symptoms and progress of these three severe cases, while differing in some respects both from each other and from those in the previous group, record well enough to be recognized as belonging to the same syndrome. Case V reached most nearly to the condition seen in the fatal cases just before death. All developed a spastic paraplegia.

General Description

The syndrome, as exemplified by the majority of cases, is ushered in by various combinations of the following symptoms: locomotor disability—taking the form of weakness, stiffness or unsteadiness of the legs; failure of vision; diplopia; pains in the feet; pain in the back; paraesthesiae in the feet; cramps; changes in the mental sphere such as depression or mental dulling. Nocturnal incontinence of urine occurred as an early symptom in three cases. Two had epileptiform seizures. Only one or two complained of cramps. Marked spasticity with or without extensor plantar responses were present in all cases. The following is an analysis of the commoner symptoms.

Symptoms	% of Cases
Difficulty in walking	53.9
Loss of visual acuity	46.0
Mental changes	41.2
Pains in feet (painful feet syndrome)	38.0
Paraesthesiae in limbs	17.4
Pain in spine	6.3
Diplopia	5.0

In the early stages there may be no objective signs apart from unusually brisk reflexes and a rather hysterical behaviour. It was observed on several occasions that on examination men who had walked to the outpatient department complaining of pains in the feet revealed exaggerated knee and ankle jerks and extensor plantar responses. After a night's rest in hospital these signs would disappear. I assumed that in these cases there was only a minimal degree of the condition under discussion.

When this nervous affliction became well recognized medical officers began to report the occurrence of increased tendon reflexes sometimes accompanied by clonus and extensor plantar responses, in ward patients suffering especially from dysentery and prolonged fevers. Both these groups of patients—those suffering from pains in the feet and those just mentioned—received special care, and I am not aware of any that failed to recover fully.

The difficulty in walking was due to a progressive spastic paraplegia with the development of the signs usually associated with it—viz., spasticity, weakness, exaggerated tendon reflexes, extensor plantar responses, and loss of abdominal and cremasteric reflexes. In just over 50% the signs of pyramidal tract involvement were confined to the lower half of the body, in about 28% the upper limbs were included, and in the remainder there were signs of involvement of the highest part of the system, with loss of facial expression, facial immobility, dysarthria, and dysphagia.

Under the conditions which prevailed it was not possible to test the visual acuity of all these patients; the loss was never severe and vision recovered rapidly which was in striking contrast to the chronicity of the cases suffering from retinobulbar neuritis. In only two patients did I find any abnormality on ophthalmoscopic examination: in one the discs were very pink and the edges ill defined; he later developed further impairment of visual acuity and became established as a case of retinobulbar neuritis. The other had well marked papillitis with exudate close to the discs; in this case the spastic syndrome was complicated by oedema of the legs and pellagra skin lesions: facial diptheria, ST malaria and later a polyneuritis affecting all limbs and both sides of the face. He made a satisfactory recovery without visual defects.

The mental changes comprised general dulling, depression, loss of emotional control, and hysterical behaviour. One patient developed ideas of persecution which persisted until his death a year later, by which time there had been considerable physical and mental deterioration. Another developed grandiose ideas which lasted many months, and a third became confused and aggressive for a few weeks.

Pains in the feet were common but this syndrome was widespread at the time as were the other signs of deficiency disease which were found associated in the spastic syndrome in not more than one third of the cases. The painful feet syndrome has been well described by J. A. Page (1946). The paraesthesiae comprised numbness and tingling and were unaccompanied by objective signs. These symptoms tended to disappear rapidly after admission to hospital. The loss of bladder control arose early in some cases as nocturnal enuresis. Pain in the spine was usually located in the cervical or lumbar region and occurred in severe cases with much rigidity and helplessness. The diplopia was usually of short duration and disappeared soon after admission. In some cases this symptom was intermittent.

Investigations

Laboratory facilities were limited and the staff was continuously at work on blood films and stool examinations. Fractional test meals were performed on three cases; the results showing one to be achlorhydric and two normal. Lumbar punctures were done on six cases and the cells and protein were normal in all.

A survey in respect of age, length of service in the East, previous illnesses, habits in regard to consumption of alcohol and type of work as a P.O.W. failed to produce any facts of significance.

Course and Treatment

The onset and progress were fairly rapid in the majority of cases and my records show that in 18 where information is available an average period of 18 days illness preceded admission to hospital; the extremes being 3 and 42 days. All non-fatal cases deteriorated for an average period of 21 days after admission. The shortest period from onset to recovery when a paraplegia had developed was 9 weeks.

Owing to the later division of the main Changi Hospital into two separate camps I am unable to give exact figures bearing on the late results of the disease in all cases. Of my original 29, 6 died (one from pulmonary tuberculosis), 9 recovered completely and 14 were left with signs of paraplegia of varying extent, of which 2 were bedridden when last seen in September, 1945.

The means available for the treatment of the earlier cases consisted in an addition to their diets of reconstituted milk (1-2 pints 0.56-1.1 litre), marmite (1-3 oz 25.3-85 g), 'marmite' (34 ml daily) for a maximum of 11 days, parenteral vitamin B₁ up to a maximum of 16 mg per case, liver extract up to a maximum of 12 ml and red palm oil (1-3 oz 28.3-85 g daily). Rice polishes, per nuts, eggs, tinned meat and fresh vegetables were given as available. It was not apparent that any addition affected the course of the disease.

Discussion

Evidence is presented that under certain conditions of nutritional deprivation a disorder characterized by signs of damage to the cortico spinal innervation makes its appearance. When severe this condition is responsible for widespread disorder of cerebral function resulting in disturbance of memory, control with quadriplegic rigidity characteristic of the decorticate animal and in some cases convulsions. As recovery occurred spastic paraplegia was the common residual state. In minor affections less evidence of the initial cerebral illness may yet be followed by a crippling spastic paraplegia or a lesser degree of spastic weakness. Complete recovery may ensue after a severe initial onset.

Spastic paralysis has been reported in severe classical pellagra. Thus Heatley-Spencer and Biggs in the *British Encyclopaedia of Medical Practice* state 'Sensory changes are common in the lower limbs and consist of various paraesthesiae and numbness. Objective sensation usually remains intact and there is no alteration of deep sensibility. Romberg's sign is rare. Pain in the dorsal or lumbar regions is common. Peripheral neuritic pain may be severe and is often a late symptom. Stiffness and some loss of power, with painful cramps in the lower limbs, are common. The reflexes are variable, the knee-jerks being in some cases exaggerated, with a spastic rigidity, and in others lost. Mental changes are important and begin with mental dullness, slow response, and loss of memory.'

Manson-Bahr, in his *Tropical Diseases* includes ptosis, diplopia, amblyopia, and rarely epileptiform convulsions among the signs and symptoms, and states that later the gait becomes uncertain and of the spastic paraplegic type. This author mentions a very acute form of pellagra, described under the title of "pellagra typhus," characterized by intense prostration, high temperature, muttering delirium, pronounced nervous tremors, generalized rigidity and convulsions. The acute cases reported in this paper seem not dissimilar.

The additional point that this syndrome arose in the course of other manifestations of vitamin B deficiency which are recognized as part of the classical picture of pellagra lends support to the view that it is itself an isolated manifestation of that disease. The B complex comprises several factors, and the experience gained in our camp suggested that there was a different time factor for each before evidence of deprivation showed itself, the mucous membrane and dermal lesions of pellagra appearing first and the nervous lesions later. It is of interest that not more than one third of the cases of pellagrous encephalopathy here reported showed other evidence of deficiency, but this lack of association was reported by Spillane and Scott (1945) in their account of deficiency manifestations among German prisoners of war in the Middle East.

Conclusion

The above findings are based on 63 cases of a deficiency syndrome, which has been given the name of pellagrous encephalopathy, occurring among prisoners of war in Singapore. There appears to be sufficient evidence to include it among the manifestations of vitamin B deficiency and as part of the pellagra symptom complex. Previous reports have been made in the literature of limb weakness and spasticity with and without extensor plantar responses (Wilkinson, 1944, Spillane and Scott, 1945, Clarke and Sneddon, 1946, Pallister, 1940), in association with other deficiency manifestations but a clear-cut syndrome as reported here appears to be unique.

My thanks are due to all those medical officers in the Changi Prisoner of War Hospital under whose care these patients were admitted, and to Dr D. Denny Brown, of the Department of Neurology, Boston City Hospital, for his help and encouragement in the writing of this article.

A scientific meeting and the resumed annual general meeting (for members only) of the Nutrition Society will be held at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C., on Saturday, Feb 22, at 11 a.m. The speakers and subjects at the scientific meeting are as follows: G. Fraenkel, Requirements of Insects of Known and Unknown Members of the Vitamin B Complex; O. Kestner, Importance of Mixed Food for Nutrition; T. F. Macrae and G. A. Childs, Nutritive Value of Food Served in the R.A.F. during the War; J. Ganguly, S. K. Kon and S. Y. Thompson, Form of Vitamin A in Cow's Milk; R. Braude, Stimulation of Growth and/or Fattening of Pigs by Synthetic Oestrogens; G. Dunlop, Nutritional Variation of Soils and Pastures on Scottish Hill Grazings; E. M. Hickmans, S. Bishop, and Y. Williams, Effect of High Protein Feeding on Marasmic Infants following Operation for Pyloric Stenosis; Z. A. Leitner, T. Moore and I. M. Sharman, Vitamin A in Rheumatic Fever. Non members are admitted to meetings of the society only by the introduction of a member. Meetings of the society are private and no unauthorized account of its proceedings may appear in the Press. Further details of the society can be obtained from the honorary secretary Dr Leslie J. Harris, Nutritional Laboratory, Milton Road, Cambridge.

Medical Memoranda

Case of Ectopia Testis with Seminomatous Change and Torsion

The following case is interesting in that it illustrates three pathological conditions: first, ectopia testis of an unusual type; secondly, a malignant tumour of that organ; and, finally, torsion. The liability of malignant change in an ectopic testis is a statistically supported, albeit disputed, fact. Gordon Taylor (1938) states that 15 out of 50 testicular tumours occurred in undescended testes. Tumours of the testis, however, are not common, and Barrington (1939) remarks that out of 9,714 admissions to St Peter's Hospital for diseases of the male genital system only 14 were testicular tumours. In our case an extreme example of undescended testicle had undergone both malignant change and torsion.

CASE HISTORY

A man aged 38, married but with no children, had recently been discharged from the Army with a clean bill of health. He had once during his service—in June, 1945—had an attack of abdominal pain, but after 24 hours' observation had completely recovered. In June, 1946, he called in his doctor one morning because of slight abdominal pain and having had several loose stools during the night. On examination there was a generalized abdominal tenderness with considerable rigidity, but temperature and pulse were normal. His doctor therefore decided to see him later in the day before coming to any conclusion. When seen during the afternoon he had increased pain, together with nausea, and there was marked tenderness in the right iliac fossa. There was also a rise of temperature to 101° F (38.3° C). He was then admitted to the Victoria Infirmary, Northwich. Here examination confirmed these findings, and a provisional diagnosis of acute appendicitis was made. It was, however, noted that the right testis was absent from the scrotum and the inguinal canal was not patent to the exploring finger. Consequently a reservation was made that there was a possibility of some morbid change in an ectopic testis accounting for the symptoms.

The abdomen was opened by a pararectal incision in the right iliac fossa. When the peritoneum was opened a quantity of blood stained fluid escaped and on exploring the pelvis with the hand a rounded mass was found in the retrovesical pouch. This was delivered and seen to be a globular mass the size of a cricket ball, which was plum coloured and had the appearance of a twisted ovarian cyst. It had a twisted pedicle 1½ in. (3.75 cm) long which emerged from the parietes at about the site of the internal inguinal ring. It was clamped, ligated, and divided near its base and the mass removed. There were no adhesions, and no difficulty was encountered. There was no sign of pelvic or lumbar glands, and the liver was palpated and felt quite normal. The wound was closed without drainage and the patient returned to bed. He recovered uneventfully.

The tumour was incised, revealing that it was the missing testis. It was sent for section to Dr W. H. Grace, who reported that it was a seminoma which had undergone torsion. The patient's urine was later also submitted to Dr Grace, who determined that the Aschheim-Zondek reaction was negative, but as this was about three weeks after the removal it could only be an indication that there was no large metastasis as yet. After discussion it was decided not to recommend deep x-ray therapy at this stage, and on this point we invite criticism.

COMMENT

Perhaps the chief interest of this case lies in the abnormal anatomy of the testis and in the complete, or almost complete, absence of symptoms as demonstrated by a successful service in the Army. The testis had picked up a complete visceral peritoneum and had come to be a free intraperitoneal organ—a very unusual state of affairs. That it had undergone torsion was perhaps not surprising after, owing to the seminomatous change it had attained the size and weight it had. Nevertheless it must be assumed that the symptoms which led to operation and ultimate diagnosis of the condition were due to torsion as no doubt was his attack in June, 1945 although this must have corrected itself, and to this fact the patient may, we hope owe his life.

We wish to thank Dr W. H. Grace for his pathology report.

Reviews

A TEXTBOOK OF GYNAECOLOGY

Textbook of Gynaecology By J H Peel, BM FRCS
FRCOG Second edition (Pp 467, illustrated 21s)
London William Heinemann Medical Books 1946

This textbook is of convenient size, and the paper and print are of excellent quality for a modern publication, though the illustrations are not perhaps of a high enough standard. The original Forsdike illustrations have been retained to a large extent, and though they do not equal those of modern American publications they are fairly satisfactory. The main criticism should be directed towards the new illustrations, particularly the photomicrographs, some of which are very poor.

The arrangement of the book is unusual and the chapter on symptoms in gynaecology is introduced towards the end. The chapter on gynaecological operations is possibly too condensed. Most teachers will agree that students do not need too much detail, but they probably want to know more than Mr Peel has included in his textbook. There is a tendency to over stress endocrinology, and some of the ingenious suggestions for the classification of disorders of menstrual function are not universally accepted. The subject is notoriously difficult, and anyone familiar with the American literature knows only too well that widely different opinions are held in that country. Another difficulty is the use of the word oestrogen in a wide sense to include all oestrogenic substances. The practice is popular with some American authors but may be confusing to medical students.

On the whole the book is well written, but there are occasional lapses in literary style. For example on page 43 there is the sentence, "The primary function of oestrogen in the body is that of a sexual growth stimulating one." Nevertheless the book is interesting, with a good classification, and medical students will be able to obtain a fair knowledge of gynaecology from it.

NURSING RECRUITMENT

Why No Nurses? By James Barclay (Pp 176 6s) London
Faber and Faber 1946

Although nursing conditions have been surveyed in recent years first by the *Lancet* Commission and then by the Athlone and the Rushcliffe Committees, and many recommendations have been made and some have been acted upon, the profession still remains under recruited. The fate of the hospital part of the National Health Service scheme depends upon the success with which Mr Bevan can court the young woman of 18 who knows quite well what she wants and has many other opportunities open to her. Mr James Barclay's well written little book *Why No Nurses?* suggests that the difficulty is not so much a question of pay—the worsening of nursing recruitment has run parallel with increase in remuneration—as a lack of private life which is supposed to be inherent in the nurse's calling. Even in her off duty hours in the nurses' home she is still psychologically attached to the hospital in a sense in which the typist is not attached to her office or the teacher to her school, but he does not make the obvious suggestion that nurses should be recruited so far as possible from the locality of the hospital in which they are to serve and be allowed to live at home. One of his proposals is that the nurse should be trained in a hospital unit rather than in an individual hospital—a conception which may be realizable through the regional hospital boards. He is critical of many things in the nurse's life, especially the matrons and their lieutenants the home sisters, and hospital administration in certain respects, he even drags in the British Medical Association for uncomplimentary reference. The author is an officer of a public health authority and sees the matter from that point of view. His 'left' sympathies are indicated by the fact that the new permanent committee which he would have the Ministry of Health set up to make constant surveys and reports on the position would include TUC representatives, a delegate member of the Socialist Medical Association and a representative of the *New Statesman and Nation*. He seems to recede a little from this advanced attitude when he says that the composition should be predominantly male.

BOOKS RECEIVED

(Review is not precluded by notice here of books recently received)

Essai de Neuro endocrinologie P G Roussy and M Mosinger (Pp 1,106 2 200 francs) Paris Masson 1946

An account of the hypothalamic hypophyseal mechanism and its nervous and hormonal connections

Man The Verdict of Science By G N Ridley (Pp 156 2s 6d) London Watts 1946

A popular exposition of the scientific study of man and society

One Hour of Justice By A C Mport MD FRCP (Pp 311 8s 6d) London Dorothy Crisp 1946

A denunciation of the conditions in which the Egyptian poor live, by the late professor of clinical medicine at the University of Cairo

Ophthalmic Surgery and Sight testing By M A Kanchan MB, CM (Pp 297 Rs 6) Mangalore Starada Press 1946

A manual intended for the use of students and practitioners

On Gout and Allied Diseases By John Hertz MD (Pp 400) London Geoffrey Cumberlege 1946

A monograph with illustrations some in colour and extensive bibliography on the normal and diseased thyroid gland. Translated from the Danish

Effect of a Carcinogenic Hydrocarbon on Manifest Malignant Tumors in Mice By S Sæmer (Pp 158 12s) London Geoffrey Cumberlege 1946

Includes accounts of experiments with 9,10 dimethyl-1,2 benzanthracene by injection and ingestion and its effect on the Crooke sarcoma, Street sarcoma and transplanted leukaemia. Translated from the Danish

Serological Studies on the Pneumococci By Erna Møller (Pp 192 10s) London Geoffrey Cumberlege 1946

An account of the author's studies of pneumococci at the State Serum Institute, Copenhagen with previous work summarized in a list of references. In English

Studies on the Risk of Infection with Bovine Tuberculosis to the Rural Population By Jon Sigurdsson (Pp 250 15s) London Geoffrey Cumberlege 1946

After an introduction on the bacteriology of the tuberculosis bacillus the author discusses ways of infection in pulmonary tuberculosis, distribution of bovine tuberculosis in man and cattle and the spread of the bovine form. In English

Studies on Impaired Fertility in Man with Special Reference to the Mite By Rieh Hammen (Pp 206 10s) London Geoffrey Cumberlege 1944

An investigation into the morphology, motility, viscosity, and virility of spermatozoa and how these and other factors are related to fertility. In English

The Dental Assistant's Handbook By G I West (Pp 104 6s) London Wm Heinemann 1946

A simple account of the dental assistant's duties and the knowledge required in performing them. Includes chapters on radiology, the psychological approach to patients and dental instruments

The Epidemiological Significance of Grouping and Typing the Haemolytic Streptococci By Jorgen Ernst (Pp 377 25s) London Geoffrey Cumberlege 1942

Part I contains a classification of haemolytic streptococci, in Part II the spread of streptococcal infections is considered, and also malarial epidemics, scarlet fever in schools and the occurrence of streptococci in the throats of healthy people. In English

The Duodenal Glands of Branner in Man By I Lindboe Christensen (Pp 267 20s) London Geoffrey Cumberlege 1944

An investigation into the distribution and quantity of the Branner glands. The parenchymal mass was found to be relatively greatest in childhood, absolutely so in middle age

Medical Disorders of the Locomotor System By F Huel-M.A., MD, MRCP (Pp 625 45s) Edinburgh Livingstone 1947

The author discusses rheumatic diseases at length and has two chapters on osteoarthritis, fibrositis, brachial neuritis, and the anatomy and physiology of the locomotor system. Many illustrations

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY FEBRUARY 15 1947

PRINTING OF THE B M J

The printers of the *British Medical Journal* on Monday this week had no electricity to turn over the machines, and by 7 p.m. on Monday night the Editor was still unable to learn from the Ministry of Fuel and Power whether it would be possible to produce this week's *Journal*. On Tuesday permission was granted to go to press this week, but the printers were still short of electrical power. For the resulting imperfections in this week's issue we apologize.

At the time of going to press we understand that we shall not be able to publish the next two issues of the *Journal*, which during the two recent world wars was regarded as indispensable to the national effort. On May 10, 1941, the *Journal's* printers were destroyed by German bombs, but production of the *Journal* continued uninterrupted. We regret that this time it looks as if it will be impossible to repeat "Operation Phoenix".

DISCUSSIONS BEGIN

The Negotiating Committee met on Feb 7 to consider the Minister of Health's response to the resolution recently passed at the Special Representative Meeting on Jan 28. This resolution was as follows:

That the British Medical Association, having considered the final results of the plebiscite and the Minister's letter of Jan 6 to the Presidents of the Royal Colleges, and desiring to secure for the people the best possible Health Service, is willing that discussions be entered into with the Minister to that end, provided that such discussions are comprehensive in their scope and that the possibility that they may lead to further legislation is not excluded, and that after the conclusion of these discussions a second plebiscite of the profession be taken on the issue of entering the Service.

Mr Bevan responded to this in the following words, as expressed in a letter from the Secretary to the Ministry to the Secretary of the B M A: "The Minister wishes me to say that he has considered the terms of the resolution and will be glad if the Negotiating Committee will resume discussions with him, in the light of that resolution, at their early convenience." As was pointed out in last week's *Journal*, the various constituent bodies of the Negotiating Committee, which, it may be repeated, is a Committee representing the whole profession and not just the B M A, had different views on the terms on which discussions on the National Health Service Act should be conducted. The three English Royal Colleges and the Society of Medical Officers of Health, for example, were in favour of the negotiations on the Regulations without any proviso. The important element in the resolution of the Special Repre-

sentative Meeting was that discussions should be comprehensive and that a possibility of further legislation be not excluded. The final point made was that another plebiscite should be taken on the issue of entering the new Service when its full details were known.

It is highly gratifying that the representatives of the constituent bodies at last week's meeting of the Negotiating Committee, at which the Presidents of the three English Royal Colleges were present, had the wisdom and statesmanship to sink their differences of opinion by accepting the terms of the Minister's invitation. The Minister wants to enter into discussions in the light of the resolution of the Special Representative Meeting, and in agreeing to this without dissent the constituent bodies of the Negotiating Committee have, by their decision, agreed to the terms of the resolution of the Special Representative Meeting. This happy solution of recent acute dissension within the profession has unified its forces and intention. The essential thing now is to foster this unity and to preserve it unimpaired through the coming months of trial by discussion. Only if this unity can be preserved will suspicion be dissipated and an effective settlement of a difficult problem be reached.

KING EDWARD'S FUND

Fifty years ago the country was preparing to celebrate Queen Victoria's Diamond Jubilee, and it was the Prince of Wales, later to become King Edward VII, who finally selected, as a suitable form of commemoration, from the various proposals put before him, the establishment of a fund to assist the London voluntary hospitals. It was called the Prince of Wales Hospital Fund, and on his accession to the throne was renamed the *King Edward Hospital Fund* for London. Contributions, many of them large legacies, have created a capital sum that now exceeds £5,000,000; about £300,000 are distributed yearly.

A characteristic feature of the Fund and one that greatly enhances its value is the care with which it investigates precisely the hospital conditions that most urgently need improvement. The Fund is not a goose laying a golden egg occasionally on the breakfast-table of some fortunate hospital, on the contrary, detailed information of two kinds is sought before a grant is made. First the hospital must disclose its financial position—the Fund insists upon a uniform system of accountancy in all hospitals seeking its support—and, secondly, visitors meet representatives of the hospital staff and discuss with them such topics as the cooking and serving of meals, the amenities of the nurses and domestic servants' quarters, the comfort of the patients, and arrangements for supervising the health of the staff. These visitors, from whose reports much valuable information has been gathered and published for the guidance of hospitals, are not necessarily technical experts and include laymen in their number as well as doctors; they are men and women of wide experience in medical and lay administration, and they usually work in pairs—one medical member and one lay. Inspectors the visitors certainly are not: there is no question of their imposing regulations on the hospitals seeking the Fund's help. They bring a knowledge

of the latest developments in administration and welfare, and the hospitals are always willing to follow their advice.¹ Various inquiries have been carried out through the visitors and recommendations made on the evidence collected by them. For example, several years ago it was found that the catering in some hospitals had lagged behind the standards set by modern knowledge of nutrition, and that whereas the special diets were often carefully designed the general catering was done with obsolete and wasteful methods of cooking, and food was served in an unappetizing manner. The once familiar patients' lament that "they always starve you in hospital" has been muted by the Fund's efforts. The Ministry of Food, under Sir Jack Drummond, analysed the meals served to patients and staff at certain co-operating hospitals, and the Fund prepared two memoranda.² The influence of these publications has extended far beyond the hospitals in the London area, and additional information for those hospitals unable to employ a full-time dietitian is supplied by a dietetic advisory service set up by the Fund. More recently the Fund has investigated the welfare, health, and recruitment of nurses,³ and it has also held a special inquiry into the prevention of tuberculosis in nurses. Its recommendations include a separate bedroom for each nurse, a pension scheme, which has been adopted by almost all voluntary hospitals, and regular medical examination. The Nursing Recruitment Service, the advisory work of which is done entirely by nurses, is designed to present nursing as the attractive and satisfying profession it can be (and to the creation of which the Fund has itself contributed so much), and to encourage and advise those many girls who at the age of 13 to 16 desire to enter it but who drift away before reaching the most suitable age for beginning training, 18, either because they are discouraged by being refused admission to the particular hospital that they had set their hearts on or because other employment at which they can start at a younger age engages their attention. The Fund has also established six preliminary training schools in London, each used by a group of the smaller hospitals, to give girls an introductory training for 9 to 12 weeks before they enter the wards.⁴ The latest special inquiry is into hospital domestic staff.⁵ The most important recommendation in this connexion is that hospitals should appoint a trained lay supervisor who would work under the general supervision of the matron.

Apart from these investigations the Fund runs certain services. Hospitals may borrow from the radium "pool," and the Radium Committee, under Sir Ernest Rock Carling, offers the services of a panel of physicists to advise radio-therapists. The Emergency Bed Service, which was started in 1938, relieves doctors in the Metropolitan area of much anxiety and vexation by informing them of where beds are available and arranging ambulance transport. In addition information given in the timetable of out-patient clinics eliminates some of the waiting that used to be a feature frequently commented upon by the patients attending them.

The passing of the National Health Service Act does not directly affect the Fund. It has, however, a most important part to play in a State health service, for money that is now allocated to the routine upkeep of hospitals will be available to benefit directly the welfare of the patients. It will be able to introduce a humanizing influence into conditions that some have feared may become mummified in the arid air of bureaucracy, its gifts will be free from Treasury control and can be the means of providing those individual attentions and comforts that prevent a patient from feeling merely a case and which no amount of paper organization ever conduces to. All hospitals within its area, including those that are now under local authority control, will be eligible for grants from the Fund, and the personal relationship maintained by its visitors will do much to keep alive the humane tradition in hospital medicine.

BURNS AND SCALDS

At this time of the year home fires are kept burning as brightly as the coal ration permits, and with this goes an increased risk of burns, especially to old people. Although the number of fatalities from burns and scalds has progressively diminished during the last forty or fifty years, avoidable tragedies still occur. In the last quinquennium of the nineteenth century the average annual number of deaths from these causes in England and Wales was 2 534, in the last peacetime quinquennium (1935-9) the number was 1,303. Nine out of ten of these fatalities, if the experience of two large hospitals is representative, arise out of accidents in the home most of which might have been prevented by simple precautions. Among elderly people the annual average of these fatalities has increased by 75% over forty years. The reduction has been chiefly among child victims, although even here the deaths from burns and scalds of the under-fives outnumber the deaths from road accidents. No doubt the elimination of the naked gaslight and the oil lamp has been helpful, on the other hand, gas and electric fires have brought new dangers, and fireguards which may be adequate for a coal fire may be unsatisfactory for the new heating. The universal cigarette cannot be exonerated. The shortening of women's skirts and the wearing of trousers has made for safety, but the change from woollens and tweeds to inflammable cotton and silk frocks and nightdresses brings new perils. Far more women than men die from burns and scalds, in 1936 the proportion was 460 to 175.

Dr Leonard Colebrook contributed to the October *Bulletin of the Ministry of Health and the Emergency Public Health Laboratory Service* a brief survey of the subject. Deaths represent only a small proportion of the accidents. For every fatality probably 20 cases are admitted to hospital, and up to 50 more treated as out-patients. Dr Colebrook estimates that the in-patients alone account for about a million days of hospital occupation every year. On the basis of an analysis of cases admitted to Birmingham Accident Hospital over two recent years he attributes many of the cases in children to lack of housing room for play except around the grate, to the absence or inefficiency of fireguards (the Children's Act, 1908, makes it a punishable offence to be without a fireguard when there are children under seven in the home, but this is often not enforced until after an accident has occurred), and in women and children to the wearing of flannelette or winecypette, which are not only dangerous by reason of their inflammability but because they tend to stand away from the body, so that they become ignited before the wearer is aware of it.

chief preventive measures must be to encourage well-designed fireguards, relatively fireproof clothing, and the use of sunken wells in the top of gas and electric stoves which would make it difficult for saucepans or kettles to be upset, and generally to inculcate a "heat sense," in the same way as training in "road sense" is given to both children and adults

HUMAN HEREDITY INFORMATION CENTRE

The International Centre for Information on Human Heredity has now been transferred from London to the University Institute for Human Genetics in Copenhagen under Prof Tage Kemp. Inquiries on detailed aspects of human heredity should be addressed to the Centre at 14, Tragensvej, Copenhagen North.

Prof F A E Crew, of Edinburgh University, in outlining the history and activities of the International Centre the other day, said that the Centre was opened in London in 1939 under the title of the Bureau of Human Heredity. The idea of forming such an international centre for the exchange of information on the subject came from Dutch geneticists at the International Congress of Genetics in 1930. During the war the Centre carried on under difficulties—at one period the staff worked in the caves at Chislehurst—but a survey of the whole field of genetics in relation to cancer was completed in collaboration with the Department of Medical Genetics of Ohio State University. The material was published in the form of a preliminary report by Fritz Blank¹ and a summary by Dr Anthony Feiling². The work on cancer included occupational cancers and chemical and physical data on irritants, hormonal imbalance, and coexistent disease. Racial data have proved of great value, and the Bureau organized a large statistical division. Among other things the Centre has compiled a synonym index, with definitions. Ultimate responsibility for the International Centre rests with the Human Section of the International Congress of Genetics, and it is this group which at the next meeting of the Congress will decide its future. The need for international financial support is emphasized.

DERELICT FAMILIES

Though the methods of anthropology were being applied to the study of our own culture before the war, sometimes in a misleading and even politically biased manner, little was revealed about that tenth of the population whose families are unable to adapt themselves to modern civilization. The mass evacuations in wartime brought to light the existence of large numbers of people who are habitually filthy, lousy, and feckless. They are the slum dwellers of town and country, and their particular characteristic is that when they are transferred to better conditions they are unable to change their ways of living: they create another slum in their new abode. Chronic ill-health afflicts them, and consequently the wage earners are usually fit only for casual labour. Low wages combined with prodigal expenditure on cigarettes and the cinema and, to a less extent, on drink lead to constant indebtedness, bills and pawn tickets accumulate like autumn leaves, and a summons to appear at the magistrate's court is a common occurrence. In their derelict and insanitary homes the drains are often choked, windows broken, and banisters long ago thrown on the fire. Father and mother (who is often pregnant) and the children (who are often enuretic) sleep in one bed. In the daytime the children play in the streets, running in at irregular hours for scraps of food at night they go to bed

late. Family discipline consists of alternate bribes and cuffs—"Chaos umpire sits."

The cost of these people to the community is out of all proportion to their numbers. They breed prolifically, the negative correlation between the intelligence quotient of a child and the size of the family to which he belongs was discussed in these columns on Feb 1 (p 185), in addition the children's education is so defective that they have little opportunity to develop their inborn faculties. Moreover large numbers of juvenile delinquents come from these homes, and, as Lord Templewood pointed out in a speech at Cambridge University recently, juvenile delinquency is the fundamental problem of crime, for the young most easily become recidivists, men and women of mature age do not as a rule become criminals.

Merely rehousing such families is a waste of time and money, they require re-education, and so encouraging were the results obtained by the Pacifist Service Units¹ during the war that it is proposed to extend the work. The Family Service Units, from whose chairman and honorary treasurer we publish a letter on page 271 of this issue, is a service formed from various organizations to take over and co-ordinate the work already being done in Liverpool and Manchester and then to extend it to London. Immediate results are not expected, for the fruits of education even in the best material, are slow to ripen, and nothing but complete re-education is of value. However, by persistent and personal endeavour it is hoped to prevent the decay spreading, to shore up the ruins, and gradually to adapt these families to a civilized way of life so that in a generation or two they will no longer exist.

JOHN HATTON, OF BATH

Mr John Hatton has now retired from the office of Spa Director at Bath, which he has filled with such distinction and ability for 36 years. Not only did he promote the efficiency and amenities of Bath as a spa, but he always strove to the best of his ability to implement the ideas of his medical colleagues and further their interests. The British Medical Association owes him a debt of gratitude for all the hard work which he put in on the occasion of the Annual Meeting in 1925, which was a conspicuous success, and since then he has been the mainspring of the many important and successful conferences, both medical and those of other professions, which have been held in the city. Visiting doctors and their patients always found in Mr Hatton a friend, anxious to give them all the help and information in his power, and everyone who has been in any way concerned in the public life of Bath will miss him sadly. His services, however, were not confined to local interests, for as chairman of the Spa Federation he did much to raise the status and reputation of British health resorts. Recently, in collaboration with Capt Cox R N (ret.), registrar of the Royal National Hospital for Rheumatic Diseases, he has compiled a report on the future organization of hydrotherapeutic treatment in Bath which is a document of outstanding merit. He has now been elected vice-president of the Federation, so can continue his interest in and give the help which he is so well qualified to afford to British spas. His successor at Bath is Mr Boddington of Buxton, who can be relied on to uphold the high tradition established by John Hatton, for whom all his friends wish every happiness in retirement.

The next session of the General Medical Council will open on Tuesday, Feb 25 at 2 p.m., when the President Sir Herbert Lightfoot Eason will take the chair.

PHYSICS IN MEDICINE

BY

Prof F L HOPWOOD, Dr J READ, Dr F W SPIERS,
and Dr C W WILSON

This is a summary of four papers read at the September meeting of the Hospital Physicists' Association. The discussion was prompted by the recent publication of an American volume, *Medical Physics* which by its comprehensive scope and list of contributors, suggested that physics played a far more important part in American than in British medicine¹. However, the wider service to medicine which physics can provide is recognized in a recent leading article in the *British Medical Journal*² which states "At present the application of physics to medicine is limited to radiology the electrocardiograph and the electroencephalograph in diagnosis and the somewhat empirical use of various forms of radiant energy in treatment, but it is highly unlikely that these represent more than a fraction of the contribution physics might make to human biology". This medical opinion which recognizes that the possibilities of physics in medicine are very much wider than the present almost exclusive concentration on radiotherapy by x and radium radiations, is widely held by hospital physicists, and has been admirably expressed by Prof W V Mayneord³. The most natural extension from this field would be the physics of diagnostic radiography, and of therapy by infra red and ultra-violet radiations, and high frequency currents, though there are probably many spheres of medical research in which physical measurement can play an important part—as illustrated, for example, by the recent research by Rundle and Wilson⁴ upon the eye signs exophthalmos and ophthalmoplegia.

Historical

The almost exclusive restriction of physics to radiotherapy can be understood from a study of its development in hospitals. The employment of physicists in the London hospitals and medical schools is a comparatively recent innovation. Early in the history of medical schools the lectures in all subjects were given by medical men. At Bart's the first subjects taught by specialists were chemistry and biology. Some time in the 1880's Donald MacAlister, later Vice Chancellor of Glasgow University, was appointed Demonstrator in Physics. He was succeeded by the late Dr Womack, immediate predecessor of the present Professor, F L Hopwood. Contemporary with Womack were Dr Fison of Guy's Dr Stone of St Thomas's, and, later, Dr Lehfeldt of the London Hospital. All of these, it is believed, were on the medical college staff and not on the hospital staff. It seems that the first professional physicist to take up a hospital appointment was the late Major Phillips, Honorary Physicist to the x-ray department of the Cancer Hospital for some years prior to 1914. Prof S Russ on relinquishing a Beit Fellowship, became Physicist to the Middlesex Hospital later head of the physics department of the Middlesex Hospital Medical College and Honorary Physicist to the hospital. Prof Hopwood was in 1919, one of the first physicists to become a paid member of the staff of a London hospital. He had been Demonstrator of Physics at Bart's from 1906, and an Honorary Clinical Assistant in the x-ray department, 1914-15. The immediate reason for his appointment was the contemplated development of deep x-ray therapy and this was reinforced almost immediately by the establishment of a radium research department to use radium recovered from war appliances and lent to the Medical Research Council by the Government. Somewhat later Prof W V Mayneord was appointed Physicist to the Cancer Hospital and subsequently such appointments at hospitals with large radiotherapy centres and at the National Radium Centres have become general.

From the first all hospital physicists have been concerned mainly with the x-ray and radium departments and to a less extent with the electrical and ultra-violet light departments. Prof Hopwood especially interested in units and standards, became secretary of the British X-Ray Unit Committee while Prof Russ became the first secretary of the Radium Committee of the Medical Research Council the Radium Commission, and the British X-Ray and Radium Protection Committee. In those early days mercury interrupters induction coils, and Lodge valves were general, and clinical dosage was based upon

the Sabouraud pastille, Kienbock photographic strips, milli-ampere-seconds, and milligramme-hours. The contrast with to-day is striking. It is probably not too much to claim that the present international units for x-ray and radium dosage, and the international recommendations for x-ray and radium protection, are due chiefly to the labours of the respective British committees.

Routine and Development Work of the Physicist in Hospitals and National Radium Centres

The use of x-ray and radium equipment has so far made the most direct claim on the services of the physicist. He must ensure its physical perfection and detect aberrations before they have affected treatments. The electrical and radiation protection of patients and staff, and supervision of the care of radium needles and tubes and their recovery if lost are his responsibility. He has developed convenient apparatus for the measurement of x-ray and gamma ray dosage, with which the output of x-ray tubes and needles can be calibrated and with the aid of substandards should be able to hold his accuracy near that of the standards of the National Physical Laboratory.

This accuracy is the foundation of control of radiation dosage and on it have been elaborated methods of computing and mapping the extent of the field of 'tumour lethal' dosage with respect to the tumour and its site. This field is as important in a radiation treatment as the operation field in a radical surgical excision, and is equally relevant to the question of the patient's survival. From a study of cases of frequent occurrence the best arrangement of beams can be chosen, the methods standardized and the radiation field computed initially for future routine use. Other cases may require individual study. Here particularly the physicist must have sufficient acquaintance with the anatomy and the nature of tumours to collaborate understandingly with the radiotherapist. This knowledge is best gained by first hand clinical contact and both can profit much from the partnership, the physicist must relate his calculations and measurements to actual lesions and medical practice while the radiotherapist modifies his technique towards the more precise ideas of the physicist—so far as human anatomy will allow. The construction of radium moulds with physical measurements to ensure the realization of the desired dose distribution, the determination of dose in interstitial radium therapy and the planning and assessment of x-ray and radium beam treatments require the closest collaboration of physicist and radiotherapist.

In addition to clinical work, work of a developmental or semi-research nature is an important function of the physicist. Apparatus has been developed for a great variety of purposes—to hold constant the x-ray output of a tube to measure dose rate and integrated dose under a variety of circumstances, to give mechanical aid in the computation of dose and the summation of radiation fields beam-direction devices callipers jigs etc. Empirical techniques have been investigated and improvements suggested—e.g. the needling of the larynx and radium treatment of the cervix.

Although for the reasons outlined the physicist's work is largely confined to radiotherapy, in a general hospital requests for assistance in other fields are received from time to time. A few random examples are the supply and calibration of thermocouples for measurement of the rate of recovery of defective circulation of a limb after sympathectomy and of skin temperatures following other neurological experiments, the installation of monochromatic illuminants for use with the slit microscope in the eye department, assistance with the polarimeter used to test the purity of insulin compounds, the development of pressure gauges to test the recovery of normal function in patients operated upon for cleft palate apparatus for the drip method of blood transfusion and for aspiration of bladders and wounds, sound insulation of Wehnelt interrupters, investigation of the protection of goggles from ultra-violet light and measurement of the heating produced by diathermy.

Teaching

There are advantages in the use of physicists directly concerned in radiological work as teachers of physics courses for the diplomas in radiology. The practical background of the physics of radiology is thus assured, and the first step

in the collaboration between radiologist and hospital physicist which is so desirable later. It is also desirable that the medical student should have a better acquaintance with the applications of physics to medical work than can usually be gained from the pre-clinical course, and the University of Leeds now provides a short course of lectures on the uses in medicine to which physics can be put. The practical experience of hospital physicists is also an advantage in the teaching of physics to student radiographers and physiotherapists.

Research

The attractiveness and efficiency of any physics department depend on the atmosphere and facilities for research. The Goodenough Committee contemplates that in a medical college the members of the staff should for half their time be free to pursue research. However, though the implementation of the Cancer Act is bound to exert a profound influence on the role and status of the hospital physicist, a former Minister of Health has stated that it is *not* the function of the authorities responsible for administering the Act to undertake research. There is thus a probability that only at some of the cancer centres will any research be undertaken. It is difficult to draw a sharp distinction between research and development. A great deal of valuable work, perhaps more of the nature of the latter, has been done in radiotherapy centres, but there has been some work of a fundamental character. The provision of *ad hoc* solutions for the succession of practical difficulties which arise in a radiotherapy department, or the development of techniques or appliances at the request of the radiotherapist should not be regarded as research. Rather it is the investigation of a problem freely chosen by the individual to satisfy his own curiosity, and followed wherever it leads. There is little danger that such problems will not be related to the work of the department in which the physicist is employed, and without the freedom of choice the best men will not find the work attractive.

If time and facilities were available much could be done in a radiotherapy department in tracing the chain of events between absorption of ionizing radiation and the biological effects produced, and this need not necessarily involve elaborate experimental work, as there is a considerable amount of knowledge regarding the processes of absorption of radiation, the energies of the electrons produced, the distribution of ions along their tracks, and the dependence of a number of biological effects on this ion density, which needs sifting, analysing, and studying with special reference to its implications for radiotherapy. Many profitable researches, not requiring great space or equipment, could be undertaken at radiotherapy centres, such as cloud chamber studies, or chemical and colloid effects of radiations, while the availability of induced radioactive chemicals will open to the hospital physicist a wide opportunity of collaborating in the study of therapy by these chemicals, or in the study of physiology.

However, many recent physical developments likely to have great importance in medicine require space and apparatus of considerable magnitude and knowledge of special techniques. There are machines for the production of beams of the heavier ionizing particles—protons, alpha particles, etc.—notably the cyclotron or ion tube energized by a high-voltage source such as a Van de Graaff machine. These beams may possibly be used directly in therapy or indirectly to produce supplies of induced radioactive chemicals or neutron beams. The betatron is being developed in the U.S.A. to give x-rays corresponding to exciting voltages of 100 million volts, while other methods are proposed which should give electron beams of very great energy, able to penetrate to the deepest tumour so that perhaps the electron beam itself may be used in therapy, rather than x-rays produced by the electrons. Radar research has developed means of generating and transmitting radio waves of very short wave-length—the order of centimetres—of energy vastly greater than has so far been available in these wave-lengths. Not only may such waves be superior for the customary purpose of diathermy, since heat could probably be far better localized than is possible in the case of longer waves but it is also likely that resonance of complex molecules will occur, with an associated biological effect. Lastly, the electron microscope provides a means of “seeing” biological structures far smaller than the resolution of the optical microscope permits.

A noteworthy point concerning these developments is that certain techniques are common to several—e.g., high vacuum technique, high-voltage technique, the generation and transmission of high-frequency oscillations, the focusing of ion or electron beams and so on. This suggests that it would be better if they were all tackled centrally, at a Radiological Research Institute by a team of men, each a specialist in one of these techniques rather than each separately at a different institution. Such an institute could also undertake the task of the development of more reliable and serviceable x-ray and associated equipment, and investigate desirable standardizations. Many industries have each established a research institute, and there seems good reason why the British x-ray industry should co-operate with the various interested medical bodies for a like purpose. Such an institution should have a hostel attached, so that visiting research workers could spend six months or so pursuing particular researches with the aid of the induced radioactive chemicals or other facilities of the institute. Hospital physicists should spend a period, from time to time, at the institute, assisting in the work, and so return to their hospital abreast of the latest developments and stimulated by association with the other workers there. In addition a hospital physicist of wide experience should be appointed to the staff of the institute, to provide a close liaison between the institute and the hospitals and indicate from his experience what techniques, etc., are feasible for routine hospital use.

Summary of Points Raised by the Four Speakers

Physics could play a much wider and more valuable part in medicine than at present, as it is now largely concentrated on radiotherapy.

The extension of physics into other branches of medicine in a general hospital is frequently hindered by points of administration and habit, which are due to the historical close association of radiotherapy and physics.

To be fully effective the physics in a general hospital should be the responsibility of one physics department, directed by a physicist under the general control of the hospital committees.

In order to serve all departments, rather than the radiotherapy departments alone, commensurate staff and laboratory and workshop facilities would be necessary. A common defect in the organization of physics in a hospital is failure to ensure that the physicist spends his time on work of the calibre for which he is paid by providing adequate clerical laboratory and workshop assistance to cope with the mass of odd jobs that continually arise.

Research provides a worth-while stimulus, and those permitted to do research work should have freedom in their choice of problem and in its development.

The large scale physical developments of great promise in their application in medicine would be best served by a research institute with a staff of specialists in the different techniques involved. The x-ray industry should co-operate, so that the institute could also undertake research into the improvement of x-ray and associated equipment, and any desirable standardization.

By a new rule of the General Nursing Council for Scotland assistant nurses who had received training for the State Register and had passed the preliminary examination before they were admitted to the Roll of Assistant Nurses will have their course shortened by at least six months if they again start training for the State Register. This concession, which shortens the normal course of three years training to two and a half years (or less in cases where the General Nursing Council permit), is confined to Scotland. In both Scotland and England, however, men and women who have had two years experience of nursing in a hospital under the supervision of trained nurses in the Services, the Civil Nursing Reserve, or other organizations can also apply to have their course of training for State registration shortened to two and a half years. Assistant nurses who want to take advantage of this new concession should apply, before they resume their training, to the Registrar of the General Nursing Council for Scotland, 5, Darnaway Street, Edinburgh, 3. #

ATOMIC ENERGY AND MEDICINE

LLOYD ROBERTS LECTURE BY SIR JAMES CHADWICK

The Lloyd Roberts Lecture of the Medical Society of London was delivered on Dec 16 by Sir James Chadwick, of the University of Liverpool. It was Sir James who in 1932 demonstrated the existence of the neutron, a discovery which made an essential contribution to the later release of nuclear energy. He took as his subject "Atomic Energy," dealing in the first part of his lecture with the nature and control of the fission process by which energy is released and in the second with its applications in medicine and biology. A summary, necessarily condensed is published below.

The Fission Process

Sir James began by pointing out that the designation 'atomic energy' lacked precision in that the energy of any fuel was latent in the atoms concerned. The characteristic of atomic energy was that it originated in the nucleus of the atom. Processes had been found which could cause a disruption of the nucleus and a rearrangement of the particles which constituted it and this rearrangement resulted in the release of a large amount of energy. For a chain reaction analogous to the lighting of a fire it was necessary that the particles emitted should be of the same kind as those that initiated it and in sufficient numbers to affect neighbouring nuclei. The fission reaction which opened up this possibility was discovered early in 1939 by Hahn and Strassmann.

In this process a neutron was captured by a nucleus of uranium²³⁵, forming a nucleus of uranium²³⁶ in a highly excited state. This immediately divided into two nuclei of roughly equal mass and at the same time some 1 to 3 neutrons were emitted and some gamma radiation. The fragments flew apart with great speed and in their passage through matter this energy was transformed into heat. They were unstable and might pass through a series of transformations emitting beta particles and gamma radiations, before reaching a stable configuration. The important aspects of the process were first, the great amount of energy released, and, second, more than one neutron was emitted in the fission.

In spite of this last fact, however, natural uranium was unable by itself to sustain a chain reaction. The reason was that the common isotope uranium²³⁸ underwent fission only when the bombarding neutrons had a high energy. It was uranium²³⁵, present only to the extent of 0.7%, which was particularly susceptible to fission. In order to make a small and efficient system which would sustain a chain reaction it was therefore necessary to undertake the difficult operation of separating uranium²³⁵ from ordinary uranium. For those purposes, however, which were of interest in biology and medicine, the limitation of size was of small importance, and it was possible by a special device to build an atomic reactor which used natural uranium.

Maintenance and Control of Reaction

To make the reaction self-propagating, Sir James pointed out, it was necessary to limit the number of neutrons which were lost to the reactor—whether from physical escape, due to either the fissile material or the system as a whole being of too small size or by absorption of neutrons by other materials which did not undergo fission. For peaceful applications it was necessary in addition to control the reaction so that the release of energy was not only continuous but took place at a predetermined rate.

Maintenance of the reaction was achieved with natural uranium by making use of the fact that slow neutrons were much more effective in producing fission in uranium²³⁵ than were fast neutrons. Slowing down was achieved by causing them to collide with light atoms, such as hydrogen, deuterium, helium, carbon etc., a proportion of the initial energy of the neutrons being transferred at each collision. The only two 'moderators' which had been successfully used were deuterium in the form of heavy water and graphite which was relatively cheap and abundant. The working margin, as regards loss of neutrons, was small, however, and some tons of uranium and graphite were therefore required.

Control depended on a delay, averaging a few seconds, in the emission of a very small fraction of the neutrons. The essence of control was therefore to make the assembly only a very small degree above the critical size for the maintenance of the reaction. The contribution of the 'delayed' neutrons was then necessary, and the control devices were given time in which to act and take charge. Instruments were used to measure neutron density and power level, and control effected by the mechanical movement of rods made of cadmium or boron both of which absorbed slow neutrons very strongly.

The power level was limited by the rate at which heat could be removed, and by the physical and chemical properties of the materials. It was a point of some importance that, whereas a large graphite pile dissipating some hundreds of thousands of kilowatts was required to produce plutonium in the amounts needed for reactors, a pile of only a few thousand kilowatts which could be cooled by air was sufficient for all general scientific purposes including medicine and biology. Peaceful applications could thus be pursued without setting up a plant to produce weapons of destruction.

Applications in Medicine and Biology

There were various ways, Sir James proceeded, not all of equal importance in which such a pile could be used in medicine and biology.

DIRECT IRRADIATION

By making a channel in the concrete wall enclosing the pile, a beam of neutrons and gamma rays could be allowed to escape. The latter alone were equivalent to those from a few tons of radium. These could be used for experimental purposes both physical and medical, but had probably very little value for any therapeutic applications.

PRODUCTION OF RADIOACTIVE SUBSTANCES

These could be produced in either of two ways.

(a) *Utilization of Fission Products*—The fission products from the uranium nucleus were themselves radioactive. Since fission took place in a variety of ways and could lead to a whole series of transformations a wide variety of radioactive isotopes was produced from zinc to the heavier rare earths, with the majority in the region of barium and strontium. The amounts measured by radioactivity were so large that it might not be practicable to deal with the main bulk.

(b) *Preparations of Radioactive Isotopes*—Radioactive isotopes of nearly all the elements could be made by inserting substances into the pile for neutron bombardment. By absorbing surplus neutrons the substances inserted were assuming part of the function of the control rods. The amount of radioactive substances which could be so produced depended on several factors, but on the average were at least a thousand times greater than with the largest cyclotron. The latter, however offered more variety, since protons, deuterons and alpha particles could all be used as bombarding particles as well as neutrons. The total number of known radioactive isotopes was about 450.

There were three main uses of radioactive substances.

(1) GENERAL USE IN RADIOTHERAPY

There was a possible general use in radiotherapy as an alternative to radium and radon, both in beam therapy and also in interstitial and intracavitary therapy.

If the hundreds of curies of mixed fission products yielded daily by the pile were separated from the uranium metal in which they were formed highly concentrated sources of radiation could be prepared which would be very suitable to replace radium in telerradium therapy. Alternatively, small blocks of uranium metal could be irradiated in the pile and used without separation. The source would not be so concentrated but the dangerous and costly separation process was avoided. In addition both cobalt⁶⁰ and tantalum¹⁸², which were suitable substitutes for radium in beam therapy could be prepared in sufficient quantity while for interstitial and intracavitary therapy several of the radio-elements would be satisfactory substitutes. A single pile of a few thousand kilowatts should produce enough material to treat at least 10,000 cases a year and to maintain several large beam units as well for telerradium therapy. It should thus provide for all requirements.

(2) SELECTIVE IRRADIATION

This type of action, on specific cells and tissues, depended on the selective absorption of suitable radioactive isotopes. For this purpose the chemical and physiological properties of the substance were of first importance, since these determined the selective absorption in the tissues which it was desired to irradiate. Further, an isotope which emitted beta particles of low energy would in general be desirable in order to limit the action to those specific tissues or cells. So far only radio-phosphorus and radio-iodine had been proved of therapeutic use.

Radio-phosphorus had been found very effective in the treatment of polycythaemia, useful in the case of myelogenous leukaemia, and of no apparent advantage whatever for lymphatic leukaemia. In polycythaemia, doses of 2 to 4 mc of radio-phosphorus caused disappearance of the symptoms and enormous relief to the patient, and remission might last for two years without further treatment. In myelogenous leukaemia results with some 150 patients had been fairly good. Growth was restrained to some extent, symptoms lessened, and there was less radiation sickness than with conventional x-ray treatment. On the other hand there was some difficulty in arriving at the correct dose, an indefinite hazard from the effects of the radiations, and life was not prolonged by more than a few months at most.

Radio-iodine had been shown to be effective in the treatment of overactivity of the thyroid, and of a particular but rather unusual form of thyroid cancer. Because of the great avidity of the thyroid for iodine, especially when overactive, the radiation could be placed within the cells which it was desired to irradiate. About 50 cases of hyperthyroidism had been treated, and in 80% the disorder had been controlled, although the duration of remission was not yet established. In the case of carcinoma only a small fraction of thyroid cancers picked up iodine preferentially, and the more malignant the tumour the less was the possibility of affecting it with radio-iodine.

On the whole, Sir James summed up, the results of this new method of selective irradiation might appear disappointing. It must be remembered, however, that the method was still in its infancy, and that its development and scope had so far been limited.

(3) USE AS "TRACERS"

This last, Sir James suggested, was the most promising medical application. Radioactive isotopes of normal chemical elements, he pointed out, had exactly the same chemical properties as the usual forms, so that if a radio isotope was mixed with a sample of the same element it would accompany the stable form through any series of chemical processes, however complicated, and could always be recognized by its radioactivity. The use of radio-isotopes also increased sensitivity of detection and estimation by a very large factor, which might be important with very toxic metals or drugs, and also permitted detection at a distance, without special purification, and sometimes without removal from the experimental animal. There was also the possibility of a continuous examination of the natural accumulation of material.

The first use of tracer methods was by Hevesy in 1923, when he employed a radioactive isotope of lead to investigate the metabolism of that element in plants. The first use of artificial radioactivity was by Chiewitz and Hevesy in 1935. They investigated the metabolism of phosphorus in rats, using radio-phosphorus as a "tracer". Since then much new and significant information had been secured some of which could not have been acquired by former methods.

EMPLOYMENT OF TRACER TECHNIQUE

There were three general ways in which tracer technique had been applied.

1 *Quantitative Measurement of Radioactivity in Samples Removed from the Body*—This was the most widely used technique and one applicable to all radio-elements. Radio-phosphorus for example could be mixed with inactive phosphorus and administered mixed with food or as an injection. Later the rat was killed the various organs and tissues removed, complex organic compounds might be isolated and the radio-activity of particular tissues or compounds measured. Findings

covered the distribution of phosphorus to the bones, teeth, liver, kidneys, etc., as to both rate and amount, conversion to cephalin and lecithin, formation of phosphatides, origin of milk phosphorus, the synthesis of haemoglobin from iron and of thyroxine and di-iodotyrosine from iodine, and many similar questions. Complex organic compounds, similarly labelled, could also be administered. Thus thiamine (vitamin B₁) had been labelled by synthesis from radio sulphur and its fate in the body had been followed.

2 *Remote Detection by Gamma Radiation*—Isotopes which emitted penetrating gamma rays could be detected through several centimetres of tissue. Their presence in a particular organ could then be detected by placing a Geiger-Muller counter over the organ. An extensive study of the iodine metabolism of the thyroid gland, in both normal and goitrous human beings, had been made by this method without surgical disturbance.

3 *Use of Photographic Action of Radiations*—Sections of tissue under examination could be placed against a photographic plate. Areas of darkening corresponded with the regions in which the radio isotope had been deposited. The sections could then be stained, and histological correlation established.

EXAMPLES OF USE OF RADIO ISOTOPES

Sir James then proceeded to illustrate by examples the use of radio isotopes towards the solution of particular problems.

1 *Permeability of Membrane of Red Cell*—The problem here was to explain the fact that, whereas the concentration of sodium ions was about twenty times as great in human blood plasma as inside a red cell, the potassium concentration inside the cell was about twenty times as great as in the plasma. To account for the maintenance of this difference, in spite of the broadly similar chemical behaviour of potassium and sodium ions and in face of the evident permeability of the cell membrane to chloride and bicarbonate ions, it had earlier been suggested that the red cell was selectively impermeable to the positively charged basic cations. By means of the tracer technique Cohn had been able to show, using "labelled" sodium and potassium atoms, that ions of both these elements could in fact penetrate the red cell, and that some other mechanism than impermeability must therefore be at work.

2 *Effect of X Rays on Cellular Division*—Hevesy had shown, using radio-phosphorus as indicator, that x rays inhibited the formation of desoxyribose nucleotides from ribose, both in growing and in full grown tissues—this conversion being one of the changes involved in the preliminary stages of mitosis. The greater part of the inhibiting reaction disappeared within a few hours of irradiation, and full grown tissue had time to recover.

3 *Blood Transfusion*—Some interesting examples of tracer technique were afforded by work carried out in the United States during the war in the study of surgical shock, and the development of methods for the preservation of whole blood for transfusion.

Two different forms of radio-iron were available. Fe⁵⁴ with a half-life of 4 years and Fe⁵⁹ with a half-life of 44 days. Both were used, one to label the red corpuscles of the recipient, and the other those of the donor, and they were distinguished by the difference in rate of decay. This device enables important investigations on the interaction of blood types to be carried out. These had clarified some points in blood transfusion and had proved to have applications in certain situations in childbirth as well as in surgery.

In addition, important and direct evidence was obtained on the potency of blood after various periods of storage when admixed with various suggested preservatives. It was by means of this method that the U.S.A. standards of blood storage were established.

Conclusion

"It can hardly be questioned," Sir James concluded, "that the development and wider use of this technique will bring rapid and remarkable progress in our knowledge of the fundamental chemical processes of the body and in our knowledge of health and disease. To derive the full benefit from this new method we must have ample supplies of these radioactive

materials. A single pile of moderate power would be able to supply all the tracer elements needed in this country. It is essentially a safe development of atomic energy, and one which, by enabling us to discover quickly more and more about the human body, may bring untold benefits in its train."

INTERNATIONAL SOCIETY OF SURGERY

The twelfth congress of the International Society of Surgery will be held in London from Sept 14 to 20. Discussions on the following subjects have been arranged by the secretariat in Brussels: Role of Penicillin in Surgical Practice (Opener, Sir Alexander Fleming FRS), "Recent Advances in Arteriography and Venography" (Opener, Prof. Dos Santos Lisbon), "Recent Advances in Vascular Surgery" (Opener, Prof. René Leriche, Paris), "Surgical Treatment of Pulmonary Stenosis" (Opener, Prof. Blalock, Baltimore), "Operative Treatment of Fractures" (Opener, Prof. Danis Brussels), "Results of Early Operation in War Wounds of the Lungs" (Opener, Dr. Rastos Ansart, Barcelona), "Results of Heparine in Surgery" (Opener, Dr. Crafoord Stockholm), "Role of Vasodilatation in Arterial Disease" (Opener, Dr. Diez, Buenos Aires), "Skin Defects Their Repair by Flaps and Free Skin Grafts" (Opener, Prof. T. Pomfret Kilner), "Recent Progress in the Treatment of Burns" (Opener, a Russian surgeon).

Members of the society who wish to take part in these discussions should send their names to the Secretary Mr. H. W. S. Wright, MS, FRCS, 9 Weymouth Street, London W1 or to the general secretary, Dr. Leo Dejardin, 141, Rue Belliard, Brussels, Belgium.

The society has a number of vacancies for members in Great Britain and Northern Ireland and for surgeons of consultant standing. Applications to join should reach the local secretary (Mr. Wright) as soon as possible. Junior surgeons who are not eligible for full membership may be accepted as associate members with all the privileges of membership except that of voting at general meetings. The entrance fee is 400 Belgian francs and the subscription payable every three years, is 1,000 Belgian francs. Subscriptions from present members should be sent to the British treasurer, Mr. Victor H. Riddell, FRCS, 68, Chester Square, London, SW1.

LADY TATA MEMORIAL TRUST

The trustees of the Lady Tata Memorial Fund invite applications for grants and scholarships for research in diseases of the blood, with special reference to leukaemia in the academic year beginning on Oct 1. Grants of varying amounts are made for research expenses or to provide scientific assistants to senior workers. Scholarships are awarded as personal remuneration, and their normal value has been £400 per annum for whole time research, with proportionate adjustment for work on a part-time basis where this has been approved. Applications must be submitted before March 31, and the awards will be announced in June. Further particulars and forms of application may be obtained from the secretary of the Scientific Advisory Committee, c/o Medical Research Council, 38 Old Queen Street, Westminster, London, SW1. The grants and scholarships are open to workers of any nationality and in any country in which it will be possible to make payments in the coming academic year. The available information on this point, regarding particular countries outside the British Empire, will be supplied to intending applicants on request.

LEVERHULME RESEARCH FELLOWSHIPS, 1947

Application is invited for Fellowships and Grants in aid of research, which are intended for senior workers who are prevented by routine duties or pressure of other work from carrying out research. They are limited to British born subjects normally resident in Great Britain, but in exceptional circumstances the trustees may waive the condition as to residence. The trustees are also prepared to consider applications from groups of workers engaged upon co-operative programmes of research, particularly from those engaged upon long-distance programmes or in institutions in which the normal facilities for research have been curtailed by the war. The duration of the awards will not normally extend over more than two years or less than three months, and the amount will depend

on the nature of the research and the circumstances of the applicant. Forms of application may be obtained from the secretary, Dr. L. Haden Guest, M.P., Leverhulme Research Fellowships, 7, Bedford Row, London, WC1. Applications must be received by March 1. Awards will be announced in July and will date from September 1.

Preparations and Appliances

A NEW LARYNGOSCOPE FOR ANAESTHETISTS

Wing-Commander R. L. SOPER, senior specialist in anaesthetics, R.A.F. writes:

Most laryngoscopes of orthodox design (Magill, Goldman, etc.) have the blade made in "C" section and the lower (short) part of the blade greatly reduces the space for manipulating endotracheal tubes. This has been obviated in the Macintosh laryngoscope by making the blade "Z" section—i.e., the lower portion of the blade is bent in the reverse direction. However, the Macintosh laryngoscope has in my view, disadvantages of its own: the principle of elevating the epiglottis indirectly does not in every case result in a satisfactory exposure of the cords. This is so with the large flabby type of epiglottis with which one not infrequently meets. Also the curved blade, though it

most cases allowing a view of the laryngeal opening, sometimes necessitates a stiffener being placed within the endotracheal tube to allow this to be manipulated around the curve.

In my laryngoscope the "Z" section of the Macintosh instrument has been retained with a straight blade which is used to elevate the epiglottis in the usual way. The blade is of full length and has a tip similar to the Magill except that a slot is cut in it. This slot, it has been found, tends to prevent the epiglottis slipping off the blade without being in any way a cause of trauma.

The new blade is made to fit the standard Macintosh handle and may be obtained separately. A small size is also made. The manufacturers are the Longworth Scientific Instrument Co., Oxford.

The fourth International Cancer Research Congress will be held at St. Louis, Missouri, U.S.A., from Sept 2 to 7. The Union Internationale Contre le Cancer having accepted the invitation of the American Association for Cancer Research the congress will be held under the joint auspices of these two organizations, with Dr. E. V. Cowdry, professor of anatomy in the Washington University School of Medicine and director of research of the Barnard Free Skin and Cancer Hospital serving as president of the congress. Of the three congresses that have been held previously, the first was in Madrid in 1933, the second in Brussels in 1936, the third in Atlantic City in 1939. No meeting of the congress has been held during the past eight years owing to the war.

Correspondence

Care of Children in Hospital

SIR—I have read and re-read with interest and profit the lecture given by Prof. Spence on the care of children in hospital (Jan 25, p 125). I am sure it will be of great interest and a stimulus to all who are engaged in this important work. Prof. Spence has given us much food for thought—so much indeed that it would be impossible to comment fully upon it within the space of a letter. One hopes that it will be a basis of much serious discussion and, if necessary, controversy among people who are interested in children's hospitals. I should like, however, to comment on one feature, and that is the "atmosphere" of a children's ward, so ably described by Prof. Spence. This masterly description should cause serious reflection and perhaps give rise to a sense of guilt. The state of affairs described by Prof. Spence is unnecessary but often only too true, and I would suggest that we, as doctors, are not entirely without blame. Too often have we looked upon the sick child as a patient presenting interesting clinical features requiring investigation and treatment. Too often do we tend to forget that while the child is in hospital the ward which houses him is his temporary home. The child is entitled, while in hospital, to have that feeling of security and affection which every home should provide. I feel that we, as doctors, can set an example. If the doctor will try to make the children realize that he is their friend and interested in them as human beings as well as patients, then the ward round might cease to be a distraction and become an eagerly awaited event.

There are numerous other ways in which the medical staff can contribute to a "happy atmosphere," provided they have an intimate knowledge of the working of a children's ward. Would it be too much to suggest that the medical student might acquire some of this knowledge by working on a children's ward during his training in paediatrics—by working I mean carrying out nursing duties under the ward sister for several days. I venture to suggest that in this way the future paediatrician would learn some valuable lessons in practical paediatrics.

Prof. Spence has pointed out the demands made on a nurse's time in carrying out the nursing treatment of small children, and has stressed the importance of an adequate nursing staff. As he rightly says, we do not realize sufficiently the extent to which an inadequate nursing staff may adversely affect the welfare of sick children. How can we expect a nursing staff—whose numbers are insufficient for the job—to nurse the dangerously ill child, nurse and comfort the fretful not-so ill child, and nurse, comfort, and entertain the child in the convalescent stage of its illness? In his lecture Prof. Spence has shown one way by which the burden may be lightened. This has one disadvantage in that it is not always reliable. Many mothers of sick infants have other family responsibilities—especially the care of the young children—which they cannot lay aside easily. Could his suggestion be carried a stage further (or should I say backward?) and the help of expectant mothers be enlisted? I have in mind the mother expecting her first baby. Her family responsibilities are light, and the experience she would gain would be useful in the months to come. It might even be the means of avoiding a future case of "mismanagement and feeding error."

Another method of easing the burden on the nurses' shoulders would be to cater for the convalescent child by providing "diversional occupational therapy." This once fashionable term has fallen into desuetude. Let us revive it in the children's hospitals but with safeguards. I would suggest that every children's ward should have the services of a teacher specially trained in bedside education methods. Such a teacher must recognize that her duty as part of the hospital team, is the special care of the child in the convalescent stage and to render that stage as interesting, pleasant, and as profitable as possible.

No doubt, Sir, many of your readers have other and better suggestions than mine to render more tolerable "the daily rhythm of anxiety, wonder, apprehension, and sleep." To my

mind it is most important that the train of thought started by Prof. Spence should not be allowed to lapse. It is not necessary to wait for the structural alterations which most of us would like to see carried out. Let us remember that "four walls do not a hospital make", it is the character and capabilities of each member of the staff which alone can provide the right "atmosphere." Let us never be satisfied with any improvement we make but always keep in mind that "achievement is but a milestone in the march of progress, the end of the journey lies ever ahead"—I am, etc.,

W E CROSBIE
Medical Superintendent

SIR—I have read with great interest Prof. J. C. Spence's article (Jan 25, p 125) on the care of children in hospital especially the question of nursing, as I am myself faced with an incredible shortage of nurses in the babies ward, where there is barely one nurse for every seven ill babies. I was very anxious to try his method of getting their mothers to look after them and have surveyed the situation with that view in mind. I found that of eight bottle-fed babies who are in the ward at present, the mothers of four have five other children to look after at home the mothers of two are ill in other hospitals, another had a partial gastrectomy here the day before, and the last baby's mother is suffering from puerperal psychosis. I envy Prof. Spence in being able to treat babies whose mothers can spare all that time for them, but I doubt that it is a practicable proposition in most children's departments—I am, etc.,

Dartford Kent

JOHN LORBER

Chemotherapy of Virus Diseases

SIR,—May I say that I agree with Dr. W. N. Leak's letter (Jan 25, p 160) protesting against the statement in the leading article of Dec 7, 1946, that there is scarcely a hint that viruses are susceptible to chemotherapeutic attack? In the case of both vaccinia and smallpox viruses there is definite evidence that they are extremely susceptible to the action of potassium permanganate, which inactivates them even when diluted to 1/100,000. This extreme susceptibility to permanganate was described and illustrated in the Medical Research Council's Special Report, Series No. 98, 1925, and greatly interested the late Sir Andrew Balfour for the following reason. During an outbreak of severe smallpox in the Sudan the cases had been treated with compresses soaked in permanganate and applied to the skin lesions with amazingly successful result. The object of the doctors was to counteract any secondary infection, but Balfour saw at the time that something more than this must be involved to account for the beneficial effect. When he read the report in question and realized the high degree of susceptibility of smallpox virus itself to permanganate, Balfour was more delighted than I ever remember to have seen him. The pronounced viricidal action of permanganate on vaccinia virus *in vitro* ceases in the presence of glycerin. From this it would seem likely that the well-established value of glycerin in conserving viruses is due to the protection it affords at their weakest point—hypersensitivity to oxidation. Bacteria are far more resistant to permanganate than viruses—I am, etc.,

M H GORDON

A Review of the Dietetic Factors in Liver Disease

SIR—While admiring the painstaking effort and industry of Prof. L. J. Wiggs in summarizing the existing knowledge on the above subject, I was a little surprised to read some of his categorical statements on the clinical features of acute necrosis of the liver (Jan 11, p 45). He states, "Jaundice is intense." Surely one of the most variable features of the condition is the depth of the jaundice. Sometimes it is slight in the acute stage, and in general experience it is seldom as deep as in cases with obstructive jaundice, such as is seen, for example in carcinoma of the pancreas or stricture of the common bile duct. It was perhaps for that reason that the old term "icterus gravis" long ago fell into disuse. This variability in the depth of the jaundice in acute liver necrosis was stressed by my father in his Lumleian lectures on toxic jaundice in 1931 (Willcox, W. *Lancet* 1931, 2: 57). He maintained that the grave signs were produced by the liver deficiency, which he ventured to call

hypohepatism and not to the retention of bile which is an associated feature. Nor did he, from his long personal experience of these cases, consider oedema and ascites as being found in this condition often enough to deserve mention, these two features would surely suggest cirrhosis rather than acute necrosis. I suggest that Prof Witts is too rigid with his 'rigid criteria' of the clinical feature of acute necrosis to convince those of us with experience of this distressing disorder.

Prof Witts definition of 'toxic jaundice' is also confusing. Hitherto this term has been popularly used to group together jaundice due to toxic hepatitis of all kinds—chemical poisons, bacterial infections, various infections (including infective hepatitis), as well as that associated, for example, with spirochaetosis, relapsing fever, and other infections. They are all classified together because the jaundice in all these conditions is caused in a similar way, that is by the toxic effect on the liver cells, and from the teaching point of view they fall naturally into one group. To confine the term 'toxic jaundice' to cover only jaundice due to chemical poisons is heterodox and confusing, it is best avoided. Thus we may avoid a classification confusing alike to the student and to those with a wide outlook on toxic jaundice, who regard the condition as one of toxic hepatitis from whatever cause—I am, etc.,

Windsor

PHILIP H WILLCOX

Enlightened Self-interest

SIR—Now that the Negotiating Committee is to be re-constituted it is pertinent to emphasize once again that the new Health Service affects the different groupings of the profession in varying respect and extent. In like manner certain of the principles laid down by the B.M.A. will be defended or conceded more readily by some sections than others. Why? Because they are or are not personally affected. The general practitioners are not only the very core of the scheme but are most radically affected. The question of the goodwill of practice, perhaps the most controversial of the principles is almost, if not entirely, concerned with general practice, and it may be argued with force that on this and other grounds the voice of the general practitioners should have a preponderating importance. Whereupon, no doubt, the purist will object on the score that we are considering our own interests rather than those of the public we serve. The obvious reply is that the public will best be served by promoting that service which will be most efficient and we believe—for many of us laying aside hypocrisy still dare to do—that the greatest spur to efficiency is self-interest.

The truth surely is that self-interest and ambition and desire for the public good are so interwoven that it is impossible to disintegrate them nor are they, properly regarded and blended, in any sense antipathetic, but rather complementary and working together for the best. Whether the purists or the puritans like it or not, the entirely disinterested person is a very rare individual indeed—a fact borne out at medical meetings as well as elsewhere. It is right therefore that they whose whole future will be vitally affected by what is decided should have an equitable and proportionate voice in that decision. General practitioners will not be satisfied to have their case sponsored by, for example, the Presidents of the Royal Colleges nor for that matter by those who are part-time consultants, part-time general practitioners, and who may look to become whole-time consultants. At such a crucial time the true general practitioner should be fully represented not only on the Negotiating Committee but on all the medical councils. Indeed it is not too much to ask that at all Divisional meetings the opinion of general practice should be sought and obtained by means of a special vote—I am, etc.,

Wirksworth Derby

E D BROSTER.

System or Person?

SIR—The older practitioners are more solidly opposed than those more recently qualified to the restrictive parts of the National Health Act. It is not fully realized that for seven years no doctor qualified after 1939 had a chance to treat a personal patient (private or N.H.I.) each patient was just a case under hospital or Service discipline without consideration for his or her personality, or home or family ties or background, or responsibilities. I have yet to meet anyone

who wishes to be other than a personal patient. Those who have been in the Services are unanimous in their dislike of the impersonal outlook. Oh the treatment is all right but you just don't count, and nobody worries until you are half-dead. It is interesting that for the most part they do not blame the M.O. but the system, though I have heard criticism of some of the younger men.

We are to be paid salaries to control certification. Thus can only mean that the State doctor will not be allowed to certify incapacity as he himself believes right and for the patient's good but to a schedule dictated by a Minister-appointed bureaucrat interested solely in keeping the sick fund solvent. Further, it implies that the certificate of a private (non-State, personal) practitioner will however honest and accurate, not be valid. Enter officialdom exit humanity—I am, etc.,

Newton Ferrers Devon

W F BENSTED-SMITH

The Plebiscite

SIR—The Council of the B.M.A. sent round a plebiscite to the members of the medical profession and we held Divisional meetings to discuss this plebiscite and sent our answer, which was "No". The Council decided to abide by the decision of the profession not to negotiate with Mr Bevan but the Presidents of the Royal Colleges then got into touch with Mr Bevan, and as a result the Council have now decided to ignore the plebiscite and to negotiate with Mr Bevan.

Would it not save a great deal of trouble in the future if the B.M.A. Council would take their orders from the Presidents of the Royal Colleges and so save us the time which we have, unfortunately, wasted at our executive and Divisional meetings? I am sure that there is no point in having any further plebiscites which will only have to be repeated until the Council get the result they desire—I am, etc.,

Camberley

LESLIE HARTLEY

* Neither the Council nor the Representative Body has ignored the plebiscite. Both have recognized that the Minister's letter has changed the situation and have responded to that change—ED B.M.J.

It's Happening Now

SIR—Had the Act provided a sound Health Service, with the interests of the patient at heart the profession would have co-operated wholeheartedly and there would have been no need for a plebiscite about Regulations. Many who abhor the political structure of the Act agreed to negotiation about details as they realized that to refuse negotiation would alienate public sympathy. To the lay Press the results of the plebiscite seem to suggest that nearly half the doctors are prepared to work the Act as it stands. Unfortunately the B.M.A. never put to us that straightforward question, or the Minister might have sent his representative along in a taxi for the second time.

The real meaning of the plebiscite is seen in the extraordinary number of doctors both in the public health service and the fighting Services who voted "No". Those in the public health service presumably chose that more sequestered life in preference to the hurly-burly of general practice and can be expected to have a fairly intimate knowledge of State medicine. But instead of 100% voting for negotiation more than a third voted against the newer and 'better' State medicine. Again, had the Act been sound one might have expected the Services to be 100% in favour with their freedom from having to send bills, collect bad debts and their assured salary independent of work done etc. The specialists (*vide* "Surgeons up in Arms" Dec 21 1946 p 960) seem to have had their birthright sold for them by their autocratic Presidents who would also appear to desire to sell the G.P.s birthright for the same mess of pottage and will have succeeded unless the B.M.A. takes an exceedingly firm line and in return for concessions to the Minister insists on amendments to the Act. The G.P.s voting showed the interesting result that the older they got the more firmly they voted against negotiation about details while the structure of the Act remained unsound. Even the youngsters voted 925 for and 1415 against but with increasing experience there were progressively more "Nos" until those in the oldest group—men who had seen their patients

marry, had delivered their children and their grandchildren, and had become family" practitioners in the true sense of the word—voted 2,782 for and 5,249 against

Unless the Act is amended what have our patients in store from the new Service under the present doctrine that the individual exists for the State? Willemsen was the opening gambit. The recent overriding of a GP who was acting on the hospital consultant's advice on diet for a patient is quite logical—if one admits the State doctrine. The patient had a cancer and would have died anyway so why feed a "useless mouth" when world rations are so short? The beloved physician does his traditional best for his patient. The State administrator to whom the patient is merely a "case" does his impersonal duty to the State. Granted the doctrine, what use has the State for incurable tuberculous patients? Why give them rations needed by the healthy? Indeed, why feed the useless mouths of those too old to work? This may become a major political problem when owing to the birth rate having fallen during the last decades there will not grow up a sufficient number of adults to support a rapidly increasing burden of old age pensioners. There is nothing illogical in the train of thought. Euthanasia for the useless to prevent the diversion of rationed food from the healthy and productive may not be so impossible as may seem once the State doctrine has been forced on us.

Before 1939 many believed that another war was too ghastly to be possible. Such "realists," with their heads in the sands of their daily round and trivial task, were disillusioned. Many could not believe Belsen to be anything but propaganda until the irrefutable facts unwillingly convinced them. In 1945 few would have thought that the Willemsen episode could happen here, but it has. It is our Munich, and we have to act now. What is the answer? Just that the individual does not exist entirely for the State, and the present political measure of potential tyranny disguised as a Health Act must be amended to give all a first-class Health Service—I am, etc.,

Dereham Norfolk

E PUDDY

Medical Certification

SIR,—I recently issued a patient of mine with a certificate stating that he required a "thermos" flask for medical reasons. On presenting his certificate he received the following letter from the Board of Trade:

Dear Sir/Madam,

I have your application for a "thermos" flask permit, with which you enclosed a medical certificate. In view of extremely limited supplies of flasks however, the exact nature of the illness must be advised, will you please therefore supply this information, stating in addition why a flask is essential.

As I was asked to deal with the matter I replied to the Board of Trade as follows:

Dear Sir

Reference application for "thermos" flask permit for Mr X, of Eastbourne, this patient is suffering from myocardial degeneration with oedema, cerebral thrombosis, and bronchitis. He is a very ill man and his health is failing. He requires an odd hot drink in the night, and since his wife is worn out by attending to him during the day it seems to me that a "thermos" flask is a reasonable request and that a permit should be forthcoming immediately.

I wish to lodge a personal protest. (1) The nature of a patient's illness is a personal matter, and I am at a loss to see why such private details as these should be disclosed to the Board of Trade (quotation from your letter, "the exact nature of the illness must be advised"). (2) Doctors these days are overburdened with the signing of certificates, forms, etc., and an effort should be made to lessen this work—I did not sign the initial certificate either indiscriminately or for fun. (3) I cannot understand how an officer of the Board of Trade behind a desk in London can possibly assess a patient's condition in Eastbourne. I earnestly plead that steps be taken to eliminate this bureaucratic stupidity.

These details I send you not as a moan from a doctor but simply to bring them to your notice in case you are not already aware of the situation. My letter alone obviously will do no good but backed by a protest from the B.M.A. it is just possible that the Board of Trade might remove their long noses from matters which do not concern them—I am, etc.,

Eastbourne

BASIL S KENT

To Negotiate or Not

SIR,—Contained in the annotation "Plebiscite Secret" (Nov 23, 1946 p 779) is the statement: "If the majority of the profession say 'No' on their plebiscite forms then the Minister will have no one else but himself to thank for such a refusal to operate the new Health Service Act, because this is what the answer 'No' will mean." Presumably this "refusal to operate" implied refusal to negotiate the Regulations of the Act as it stood and as it stands now. I do not know how closely this statement expressed the intentions of the Council but subsequent events showed that the Council was in fact prepared to follow the wishes of the simple majority in the plebiscite.

The more recent decision to reopen negotiations, so lamely represented as the result of a more conciliatory attitude of the Minister, has restored in the minds of many practitioners the old mistrust of the Council's ability to represent them, and aroused bitter recollections of previous vacillations in policy. If in fact the Council's change of tune does bear relation to the expressions of personal opinion by the Presidents of the Royal Colleges it seems reasonable to point out that these were only another three votes to offset the larger majority of "Noes" expressed by doctors with closer associations and deeper knowledge of the public, whose best interests are at the heart of us all. So yet again

"the native hue of resolution
Is sicklied o'er with the pale cast of thought"

—I am, etc.,

ANTHONY ALMEN

Aspiration of Acute Pleural Effusions

SIR—I would like to congratulate Dr E A Wood on his letter (Jan 25, p 159) concerning the aspiration of pleural effusions. I wish that the indications and contraindications for removal were as clearly and correctly stated in all medical textbooks.

In the hospitals I visit I have often found that the M.O.s have only a vague idea of when and when not to aspirate. I do feel, however, that pleural effusion cases should always have a small specimen of fluid withdrawn for diagnostic purposes—I am, etc.,

London N7

J WALLACE CRAIG

Curare

SIR—I hesitate to enter into argument with Dr Massey Dawkins (Jan 18, p 111) and Dr A J Gray (Feb 1, p 196) on the subject of curare, for their experience with this drug must surely be much wider than mine. At the same time I cannot but disagree with Dr Massey Dawkins over the post-operative condition of patients who have been given curare. In my small series of cases I can only feel delighted with the results, and, on questioning, the nursing staff appear to be equally satisfied. Dr Gray, in his excellent reply, dealt with the points raised, but perhaps one might be allowed to elaborate further.

With each administration of an anaesthetic agent there are well-known difficulties and dangers to be borne in mind avoided, and, less frequently, remedied. When dealing with curare the points to be considered are profound muscular relaxation with limited respiratory excursion, which together lead to some degree of anoxaemia, increased carbon dioxide tension, decreased venous return to the heart, and some fall in blood pressure. All these are dependent upon the dose of curare and the speed with which it is given. Little has been written about the rate of administration, although L. Watter (1944) reports that in one case a rapid injection of 2 ml of "intocostryn" near completion of an operation resulted in severe respiratory depression and Lundy (1945) states that rapid injection can prove fatal. It would seem wise, then, always to inject the drug slowly. As regards size of dose there is a wide variation between 9 mg and 30 mg, in my experience required to produce upper abdominal relaxation in adults. The dose should not depend upon the patient's weight but rather upon the patient's needs.

Reduced Dose . . . Increased Potency

'Hepastab Forte' contains all the known anti-anaemic factors of liver and has been so concentrated that 1 c cm contains the anti-anaemic factors previously contained in 2 c cm. Each 1 c cm of 'Hepastab Forte' is obtained from 100 gm of liver and is therapeutically equivalent to 4,000 to 5,000 gm of fresh liver by mouth.

GOLD THERAPY

GOLD therapy now takes a foremost place
in the treatment of rheumatoid arthritis.
Toxicity, formerly of sufficient severity to de-
tract from its general usage, has been materially
reduced by a more careful selection and man-
agement of cases, a much lower scale of dosage,
and the development of less toxic gold salts.
Crookes Auro-Calcium, a finely divided
aqueous suspension of calcium aurothiomalate,
provides an appreciable contribution to this
reduction of toxic effects.

With larger doses of curare there is considerable limitation of respiratory excursion, and it is not sufficient to stand some yards away from the patient and observe that he is breathing. There comes a time when this breathing is insufficient for the patient's metabolic needs and so it is imperative long before respiratory arrest is likely to set in that the anaesthetist intermittently compresses the rebreathing bag thereby favouring respiratory exchange and avoiding pulmonary stasis. A high concentration of oxygen in the inspired gases seems to be beneficial and should there still be shallow breathing at the end of the operation one should not hesitate to give prostigmin. When breathing has returned to normal hyperventilation with carbon dioxide and air will introduce the inert diluent nitrogen into the alveoli and thus help to guard against atelectasis. If these precautions are taken in every case then there should be no need to worry about respiratory depression during the immediate post-operative period and little fear of pulmonary complications at a later date.

Since curare is non-toxic, then in an anaesthetic sequence in which it is used one need only consider the slightly toxic effects of the small amount of anaesthetic agent required to keep the patient asleep. Dr Gray quite rightly states that Crile's theory has been invalidated. R. T. Knight (1944) goes further by saying that deep general anaesthesia is more damaging and more shock-producing than even the trauma of surgery. Surely then the maintenance of light anaesthesia is a prophylactic against shock. Light anaesthesia is easily maintained with non-toxic nitrous oxide but I do not think that this is entirely satisfactory with curare since the shallow breathing associated with the latter tends to increase the anaemia usually present with the former.

The majority of the cases in which I have used curare have been upper abdominal operations and/or ill patients and in these cases an intravenous drip is often required before, during, and after the operation. "Pentothal" is always used the initial dose being supplemented when rise in pulse rate—a sign of lightening anaesthesia—occurs. Usually an endotracheal tube is passed under direct vision and pure oxygen is administered throughout the operation. Under these conditions perfectly satisfactory anaesthesia and convalescence are ensured—I am, etc.,

Truro Cornwall

G. V. S. WRIGHT

SIR—Dr Massey Dawkins (Jan 18, p 111) has drawn attention to three post anaesthetic complications following the use of curare—viz shock, respiratory depression and paralytic ileus. While these conditions unfortunately do occur may they not be attributed to an overdose of curare—that is, a quantity in excess of that necessary to produce the desired effect?

At present there appears to be a tendency to use curare in dosage sufficient to produce immediate absolute relaxation, with little regard to individual susceptibility. The latter may be of more importance than the weight or physical fitness of the patient and the adoption of a small initial test dose" (5–10 mg tubocurarine chloride) followed by minimal additions may lessen these complications. I have observed marked hypotension following the administration of curare in light and deeper anaesthesia—even before the incision has been made. This is presumably due to the action on the autonomic nervous system in the curare-sensitive subject—I am, etc.,

Llanelli Carmarthenshire

D. S. JONES

Curare or Magnesium Sulphate?

SIR—We have used magnesium sulphate as a relaxing agent in anaesthesia in a few cases with unconvincing results. One woman aged 32 was given 'pentothal' 0.5 g followed by 20 ml of 25% magnesium sulphate solution intravenously and nitrous oxide and oxygen for appendicectomy. Relaxation appeared to be good but it is difficult to say what part the magnesium sulphate might have played in this. A man aged 38 was given 'pentothal' 0.5 g followed by 25 ml of 25% magnesium sulphate with cyclopropane and oxygen for repair of an incisional hernia of the upper abdomen. In spite of deep cyclopropane anaesthesia relaxation was not as good as with curare. In another case laryngoscopy and orotracheal intubation were performed without difficulty in a healthy woman

aged 24 after "pentothal" 0.5 g and 20 ml of 25% magnesium sulphate. Laryngeal irritability appeared to be less than after "pentothal" alone.

There were no adverse side-effects and respiration was not obviously affected in any of the cases. Magnesium sulphate has been used to mitigate convulsions in shock therapy,¹ and it is said to have bronchodilator and antihistamine effects.^{2,3,4} Anaesthesia has been produced with magnesium sulphate,⁵ but muscular relaxation appears first. It seems that if magnesium sulphate is to be used instead of curare much larger doses must be used than the 0.5–1 ml of 25% solution suggested by Dr W. F. Cooper (Feb 1, p 197)—We are, etc.,

Prognosis of Hypertension

SIR—Your contributor writes in the annotation on "Prognosis of Hypertension" (Jan 25, p 144) discussing Bechgaard's monograph: "By hypertension was meant a blood pressure of not less than 160/90, the average was 190/110 taken after 15 minutes' rest."

But although Bechgaard's material consists of patients who had a blood pressure of 160/100 or a systolic blood pressure of 180 mm at the first examination he defines normal blood pressure as being 140/90 mm. He regards people with a B.P. of more than 140/90 mm as hypertonics even if they be over 40 years of age. He admits that "with this limit a very large number of older people (in case of the oldest more than 50%) are regarded as hypertonics." This would hardly be accepted by English and American observers who regard as raised blood pressure in people over 50 a reading of 170/105 taken under proper precautions—I am, etc.,

Gynaecomastia

SIR—It may be of interest to your readers to know that this condition is relatively common among lepers and cases may be seen in any large leper colony at almost any time. It has been described by Dr James L. Maxwell in his textbook *Leprosy: A Practical Textbook for Use in China*. It is associated with leprosy orchitis leading to atrophy of the testis followed by partial or complete sterility. It is commonly a bilateral condition and appears to be entirely painless—I am, etc.,

London SW 16

STEPHEN D. STURTON

"Anaesthesia" or "Analgesia"?

SIR—I am not concerned with the polemics of Dr F. W. Roberts (Dec 28 1946 p 1007) and Dr J. N. Fell (Jan 18 p 115) but I must take the latter to task for being misleading apparently because he thinks anaesthesia is more euphonious than analgesia and would make a more charming name for a girl than would the latter. The statements he makes might cause some members of the profession to think that those who chose these Greek words for descriptive purposes in their anglicized forms had been guilty of careless or bad selection whereas this is not the case.

Dr Fell states that there is no distinction between the words in Greek, that distinction does, however, exist in precisely the way which is intended in their anglicized forms. Anaesthesia (ἀναισθησία) is used by Plato as a noun to mean "want of perception" as meaning "stupor," and in the same work he uses it adjectivally to mean "not subject to the senses" or "insensible"; it is also used as an adverb in Isocrates in an exactly similar way. On the other hand analgesia (ἀνάλγησις) is used to describe "want of feeling," and the adjective ἀνάλγητος to describe "without pain", but let us discard the particle ἀν and look at the parent words αἰσθάνομαι and αἰσθησις are used without exception to describe "perception" in one form or another, while ἀνέω, ἀγγισις, and ἄλγος are always used to convey the "sense of pain."

I do not think I need to carry the matter further, but I would like to remark that spinal "anaesthesia" would be more properly described as spinal "analgesia." I admit that Liddell and Scott quote Demosthenes as having used ἀναλγησία in the sense of ἀνασθησία, but I do not think the compilers of the volume (even in their first edition of 1843) had in mind such a distinction being drawn, if they had I am sure they would have disagreed with Dr Fell, who selects this isolated instance to make the sweeping statement in his letter. Nowhere in Liddell and Scott can I find that "the adjective derived from analgesia was used to mean, 'very painful', the particle ἀν would necessarily cause it to have precisely the opposite meaning, however, my lexicon and I are of a much earlier vintage than Dr Fell and his edition of the lexicon and it may be that the translation of the classics is "sair altered noo." I am, however, συνπαθητικός with Dr Fell that he is a Cambridge man and has not enjoyed the advantages that accrue in the home of Liddell and Scott—I am, etc.,

GILBERT R. A. ARMSTRONG

Diet and Canine Hysteria

SIR,—In further reference to the letter (Feb 1, p 200) I sent you about a fortnight ago on the above subject it may interest your readers to know that I have just received a communication from the director of the National Veterinary School at Lyons, France. Prof. A. Brion says that "fright disease" or hysteria has been rife in France especially in the south. All ages and all breeds of dogs seemed equally susceptible. He says, further

"In France we do not believe there is any connexion between diet and canine hysteria. We have observed no reaction caused by the feeding of biscuits to dogs and it has been proved in practice that the biscuits for dogs which we have had at our disposal were not harmful. mongrels which received only the scraps from the kitchen were equally affected."

"These are the arguments upon which we have reached the conclusion that biscuits do not play any part in the cause of canine hysteria. In any case, in France flour is not subjected to any bleaching or improving treatment. We know only of a poor quality flour of 85-90% extraction and (during the occupation) no extraction. Therefore our dogs suffering from hysteria eat bread made without any addition of chemicals to the flour. That is why the work of Sir Edward Mellanby, although very interesting does not explain all cases of hysteria, and, in particular, the cause of the French hysteria is quite different."

These facts appear to bear great significance and seem to show that some other factor in the aetiology remains to be elucidated. In addition we do know that a large number of dogs in England subsist entirely upon horse flesh, and yet they too are not immune from hysteria—I am, etc.,

London N W 11

HAMILTON KIRK

Endocrine Receptors

SIR—In your editorial review (Jan 18, p 96) of the extremely valuable paper by Mr Aleck Bourne (p 79) on "Endocrines in Gynaecology"—a paper characterized by exceptionally wide experience and deep thought—you state, in relation to his conception of the reactivity of the organs to hormone stimulus (endocrine receptors), that "it seems strange that an idea so obvious should not have received closer attention in the great mass of work that has poured out in books and journals of all kinds in the last two decades."

I think that such a comment is probably doing an injustice to several endocrinologists. Certainly from my own writings I can with ease choose the following brief extracts to indicate that reactivity of the end organs has been considered as playing an important part in endocrinology, as in other branches of physiology and medicine. Thus, in the introduction to *Major Endocrine Disorders* London, published in 1938, I stated, "The reaction of the tissues to hormones, which is variable is also important", and then, after giving examples I end the paragraph with the sentence, "The reactivity of the tissues, therefore, is an important factor in determining the effects of hormone secretion." In a paper on "Endocrine Therapy" in 1939 (*Practitioner* 143, 502), I stated, in regard to psychological

impotence and the failure of testosterone propionate in this condition "Since these doses are much greater than those that are effective in a complete castrate, it would seem that psychological processes can not only prevent an endocrine gland from functioning (e.g., anorexia nervosa) but can apparently prevent a hormone circulating in the blood in supernormal concentrations from acting on an end organ." Finally in a 'Discussion on Exophthalmos' at the Royal Society of Medicine (*Proc Roy Soc Med* 1945 38 666) I put forward the theory that "if it was accepted that the pituitary thyrotrophic hormone produced exophthalmos both in Graves's disease and in the exophthalmic ophthalmoplegic group in the latter the thyroid was incapable of responding to the thyrotrophic hormone."

I think, therefore, you will agree that the importance of reactivity of tissues or of end-organs, has been emphasized in endocrine literature. These statements of fact in no way detract from the enormous value of Mr Bourne's fundamental observations nor from the usefulness of his term, endocrine receptors. May I add that I am very heartily in agreement with the views expressed in your leading article as to the need for a team of workers with adequate equipment to undertake fundamental research in this important field of endocrinology—mainly that dealing with the sex hormones—I am, etc.,

London W 1

S. L. SIMPSON

Trilene in Labour

SIR—I should like to make a few comments with regard to Mr D. M. Stern's letter (Feb 1, p 199). As long as the limitations of trilene are recognized the drug is, I think, a most useful addition to the armamentarium of the anaesthetist. I have not had any personal experience of its uses in labour but general practitioner friends are enthusiastic as to its efficiency as an analgesic and its simplicity of administration particularly by means of Freedman's inhaler, apart from cheapness and portability.

For general surgical procedures I find it a most useful adjuvant to nitrous oxide and oxygen in cases where these gases by themselves would not be of sufficient potency to produce a smooth anaesthetic, while a minimum amount of additional trilene is all that is needed in most cases. Trilene is relatively non-irritant, so that the introduction of the vapour into the circuit produces practically no disturbance of the respiratory rhythm, and induction is therefore rapid. This factor is, incidentally, of importance in a busy operative session. Trilene in small amounts appears to have very slight, if any, post-operative toxic effects. Again, its non-inflammability makes it a useful anaesthetic agent if diathermy is to be employed. But not only is any degree of relaxation very difficult to obtain with trilene, also it is generally recognized that it is dangerous to "push" the drug. My own practice is to decrease the flow of trilene directly an uncomfortable tachypnoea occurs and, if this still persists, to change over to ether or some other agent.

It therefore would appear likely that to procure the necessary relaxation a higher percentage of trilene was used in the cases of caesarean section quoted than was conducive with safety. It would be interesting to know whether there were any signs of cardiac abnormality prior to death. I have also found trilene most useful for inpatient dentistry. Used nasally as an adjuvant to gas-oxygen, a smooth anaesthetic can be procured for a total clearance allowing the dental surgeon ample time for careful and unhurried manipulations, while the patient recovers consciousness almost immediately after removal of the nose piece. Bleeding does not appear to be increased—I am, etc.,

Amersham Bucks

BERYL L. HARRISON

SIR—Mr D. M. Stern (Feb 1, p 199) has made some interesting comments on the use of trilene in midwifery. The figures given for mortality in caesarean section are certainly alarming—i.e., 5 deaths in 82 cases. One wonders why its use was persisted in after, say the first 2 or 3 fatalities.

I have used trilene for women in labour over a period of some years and I have not had reason to regret it. Some time ago I described my experiences using a Clover or Hewitt's inhaler. Since then a number of correspondents have written giving favourable impressions. I have used the drug in

approximately 150 cases, and I would say that it is safe if the following precautions are taken (1) An attendant should be present during the administration, (2) it should be given only in small quantities if uterine inertia is present, (3) probably it should be avoided if there is evidence of liver damage—I am, etc,

Northallerton Yorks

D C DEVITT

Endogenous Depression in General Practice

SIR—With reference to the two communications from Mr H I Deitch and Dr P E F Frossard (Feb 1, p 208) under the above heading I think it is only fair to point out that since early 1945 we have been running out-patient clinics at the mental hospital for just this type of case, and have now had to increase our clinics to four days per week (two male and two female), where electro-convulsion therapy is used on an average of about fifteen patients per day.

Since this out patient ECT clinic started we must have treated some 200 patients with good results. Patients of this type appreciate tremendously the fact that they are able to obtain treatment without having to enter a mental hospital as a voluntary patient, and, of course but for the day upon which they attend, they can continue their normal occupation for the remainder of the week. We ask them to have a light tea and toast breakfast, and stipulate that they must be accompanied by someone, owing to a confusion which may well occur after treatment. In fairness to other mental hospitals, I do not think the situation here is unique. No single patient has ever raised any objection to coming to a mental hospital for treatment as an out patient—I am, etc,

Broms Grove Works

A -SHEPHERD -

SIR—I am obliged to Dr A Knyvett Gordon for his letter (Feb 1, p 198) in reply to mine, and appreciate that he writes sincerely and honestly. I submit that all that I have said is perfectly accurate and that my desire is to be constructively helpful, which certainly cannot be obtained by burying one's head like an ostrich and pretending that all is well. Dr Gordon asks whether I have ever worked in a mental hospital. The answer is in the affirmative that I have seen many cases treated by electro convulsive therapy, that I have given this treatment to patients myself, that I have done most of the work for the DPM, and that I have refused temporarily several appointments as medical officer in mental hospitals for private reasons. I trust this will reassure Dr Gordon.

Under the term endogenous depression, as your correspondent will know, may be ranged a large number of conditions, among which anxiety neurosis and manic-depressive psychosis may be placed in their proper perspective. But I am concerned not so much with nomenclature but with the accuracy of the diagnosis, which of course depends on the diagnostician, but of paramount importance in my opinion, is a searching investigation into the conditions under which the diagnosis is made, which may make all the difference between tragedy and farce. A case of anxiety neurosis may be cured easily by an expert psychiatrist, but greatly aggravated by a bad psychiatrist. Circumstantial or false evidence may hang a man and this may happen also in a neurotic case, where inexperienced psychiatrists may be misled into giving a turn to the actual facts of the case. As regards conditions in some mental hospitals, Dr Gordon makes a very poor excuse for them. I myself have witnessed and can testify to unbelievable conditions which are corroborated by other people and a mass of correspondence. I quite agree that there are many intelligent medical officers who are keen on the curative side of their work, but I maintain that there are not a few who have been or are practising psychiatry or mental work who are quite unfitted for this dangerous subject for a variety of reasons.

Would Dr Gordon really have us believe that he is satisfied with the system and law in mental hospitals as it exists to-day? I myself would suggest that it is chaotic and that it is manifestly clear that a Royal Commission on the whole system and mental laws is long overdue. Obviously if doctors are implicated they must be strongly tempted to whitewash themselves. The present system is left wide open to the abuse of unscrupulous people or practices. A serious defect in the existing machinery is that doctors habitually are influenced

by statements by relatives, although such statements may be unknown to the doctor, be motivated by pure malice. As regards the relative doctor-patient relationship to which Dr Gordon alludes, I know of a case where a man was brought to the verge of a breakdown by the abominable and vicious behaviour of his wife, who caused him and his family unbelievable sorrow and anguish, and then by a fantastic chain of circumstances secured his admission into a mental hospital. Yet this type of case can be multiplied many times, it constitutes a grave social evil which we are tackling the wrong way. The man came out of hospital a shocking wreck but recovered by keeping as far away as possible from a psychiatrist. It is very nice for psychiatrists to smugly have armchair discussions on treatment, but they forget the elementary principles which are essential in the rehabilitation of an injured patient, and these are that a man should have complete and prompt rectification of a conglomeration of injustices, and that the guilty should be punished.

I would note a few extracts from recent editions of the *Journal* made by psychiatrists themselves to the effect that the mentality of the mental hospital doctor is often far below that of his patient, the use of indiscriminate electrical treatment without previous psychotherapy is far too prevalent and bad the tendency to ladle out electrical fits like aspirins must cease the admission by the superintendent of a mental hospital that out of several hundred cases receiving electrical treatment in that hospital there was not a single patient that did not look forward to it without fear, that we now stood at the dividing line in medicine about which there could be no compromise and that many experienced psychotherapists have stated that patients who have had electrical treatment have afterwards come to them without its having done them any good at all. Perhaps Dr Gordon would kindly let me have his observations—I am, etc,

London NW 11

A LIONEL ROWSON

Family Service Units

SIR—One of the most baffling and intractable problems in rehousing the population is to be found in the below standard families and homes still existing in our cities, the publication of *Our Towns* (Oxford University Press, 1943), with its revelations from wartime evacuation experience must have brought this home to many people who were unaware of the facts. During the war, at Liverpool and Manchester, pioneer experimental efforts to develop methods of rehabilitating such families through intensive and patient personal service, combined with practical assistance and social education in the home, have yielded encouraging results. Of the particular sub-standard homes dealt with in the majority of cases an improvement in conditions has been brought about, and in a number of cases radical and permanent change was effected. In addition definite instances can be cited in which families were saved from deterioration and squalor by the timely intervention of the service.

With these results before us the time has now come to establish on a wider scale a service which it is proposed to call Family Service Units, and a responsible National Committee has been formed with the co-operation of the following organizations, who are directly concerned with the problem: the National Council of Social Service, the Family Welfare Association, the National Society for the Prevention of Cruelty to Children, the National Association for Mental Health, the British Federation of Social Workers, the Committee on the Neglected Child, the Salvation Army. Individual members of the National Committee include the Archbishop of York, Cardinal Griffin, Mr John Watson (Chairman of the South-east London Juvenile Court), Sir Lancelot Keay (City Architect and the Director of Housing Liverpool), Rt Hon Margaret Bondfield, Mr Seebohm Rowntree. The co-operation of the Ministry of Health, the Ministry of Education, the Home Office and the Assistance Board has been promised.

The service will not be costly compared with the cost of these families to the community, to which to quote from *Our Towns* 'they are a menace out of all proportion to their numbers', or compared with the alternative cost of prisons, institutions, homes and other efforts to deal piecemeal with the problem, still less compared with the value of the

from disintegration and families enabled once again to take their place as self-directing and self-respecting members of the community. Co-ordination of existing work and the co-operation of all agencies concerned with the problem are essential. The aim of FSU is to provide a service at the disposal of other departments and bodies to be used by them on particular cases needing specialized treatment.

The committee plan first to take responsibility for the existing work in Liverpool and Manchester, and then to establish a new unit in London as soon as personnel becomes available. The keynote of successful work in this field must be friendship, and the work will call for personal self-sacrifice of a high order. The work of the committee will continue for some time to be experimental.

The problem family fails to utilize or benefit from such facilities for its betterment as exist at present. Rehousing, family allowances, and a national medical service are not enough. This is a task in which voluntary effort and personal service in the home must play a preponderant part, and it is a task in which personal service alone can be successful. Among the objects we have in view is a comprehensive investigation into the nature, extent, and causes of this form of social subnormality. A two years' period will, we think, be sufficient to establish the facts, and we ask for a sum of £15,000, which is sufficient to support the existing centres during that time and to establish one new centre in London.

Information will gladly be sent to anyone interested on application to the Secretary, Family Service Units, at 85, Clarendon Road, London, W 11. Donations will be gratefully acknowledged by the Honorary Treasurer, Lord Balfour of Burleigh at Lloyds Bank, Limited, 71, Lombard Street, London EC 3. Signed on behalf of the National Committee—We are, etc

D BOWES LYON,

BALFOUR OF BURLEIGH
Honorary Treasurer

London W 11

Nylon for Buried Sutures

SIR—For many years silver wire and silk-worm gut have been used to suture fractured patellas. Silk of various types and linen thread have been used for strength in ligature of main vessels and as suture material in hernias. Then the autogenous fascial graft was hailed as the best method of repairing large or recurrent hernias. Kangaroo tendon was used for a time, but one hears very little of it now. Thin silver wire, silk, and linen have been used for suturing the abdominal fascia in elderly or debilitated patients or those with a chronic cough, to give added strength and allow the patient to get up safely with a shorter time in forced reclining posture.

For the past two years I have been using nylon as a buried suture, and felt it worthy of an added word to what has already been written about it. I have used it extensively to suture the abdominal fascia in debilitated patients with weakened musculature, for the mid-line incision in abdomino-perineal excisions for carcinoma of the rectum, in upper abdominal operations where a long incision is necessary, etc. I have also used it in direct, recurrent, and large inguinal hernias and in incisional hernias as a filigree mattress, first doing an ordinary repair with stout catgut and then making an interwoven mat of nylon without tension. So far, I am pleased to say, it has proved extremely satisfactory and has produced no ill effects except that some patients have noticed a small hard lump in the scar where the knot is made.

Comparing it with silk or linen it is more difficult to knot securely, but so far there has been no trouble should sepsis occur, which has often made it necessary to remove silk or linen from the wound weeks, or even months, later. One patient who required an extensive bowel resection and was very debilitated had marked sepsis, and the skin wound broke down on the eighth day. The nylon in the abdominal fascia was visible in the wound and we feared the worst, but the sepsis cleared up, the nylon held firm, and the wound healed over it by rapid granulation. Compared with fascial graft it is easier to suture with, it shortens the operation, avoids the damage to the fascia lata, and appears to be equally efficient. Compared with fine silver wire it is less rigid, easier to knot, and, I think, equally efficient.

Nylon has been found a very suitable material for buried sutures. I do not think it useful as a ligature for main vessels, as it might cut through the wall and is difficult to tie securely. It withstands sepsis without maintaining or prolonging it. It can be used for continuous suture or as a reinforcement filigree. I would be pleased to hear of the results of others who have tried it—I am, etc,

Tonbridge Kent

N R HOUSTON

Surgical Aspects of Roundworm Disease

SIR—Capt F Barber's article (Jan 11, p 49) under this heading interested me as I dealt with a case in 1934 in which the surgical aspects were definite and urgent. The two cases on which Capt Barber operated leave some doubt as to the connexion between the worm infestation and the surgical lesion. The removal of some of the worms by incising the intestine and milking them towards the opening is difficult to justify.

My case was a girl aged 9 years with classical symptoms and signs of acute appendicitis of obstructive type. On laparotomy a curious picture presented itself. The caecum and most of the small intestine were crowded with roundworms. The appendix and its mesentery had undergone torsion, and the whole length of the appendix was black but not oedematous—indicating that the arterial and venous circulations had been interrupted simultaneously. The cause of the torsion was the peregrination of a baffled roundworm after its adventurous head had reached the distal end of the appendix. The proximal half of the worm was extracted from the caecum as the appendix was removed the stump being ligatured and buried *secundum artem*. Recovery was uneventful, and anthelmintic treatment resulted in the passage of a satisfying number of roundworms—I am, etc

J F E GILLAM

Surgical Treatment of Chronic Frontal Sinusitis

SIR—Like Mr V E Negus (Jan 25, p 135) I am a strong advocate of the external operation for chronic frontal sinusitis and the procedure that he suggests is almost identical with the method that I described 25 years ago and have practised ever since. I think, however, that he dismisses somewhat too lightly the possibility of cure by intranasal means. There are many cases in which the outflow through the fronto nasal duct is hindered in addition to those mentioned by him, by groups of cells massed round and impinging on the duct itself. I agree that it is not possible to clear all the anterior ethmoidal cells by intranasal means, but the main mass can be dealt with safely and the way opened for the passage of graduated copper bougies into the sinus itself. These crush the high fronto ethmoidal cells out of the way without damaging unduly the mucous membrane of the duct. When the largest bougie that the bony ring guarding the floor of the sinus can take has been passed, it will be found that in many cases adequate drainage is assured.

The failure of the operations of Max Halle, Ingals, and others is due to the fact that the way into the frontal sinus is cut or rasped, with consequent formation of exuberant granulations from the raw surface, the formation of new bone, and subsequent stenosis. The 'bougeing' of the fronto nasal duct is not altogether easy, but with an appreciation of the anatomical disposition and a development of the tactile sense a considerable measure of success may be looked for—I am, etc,

London W 1

WALTER HOWARTH

Acceleration of Wound Healing

SIR—In the annotation "Acceleration of Wound Healing" (Oct 12, 1946 p 548) you refer to work on the effect of tissue extracts on wound healing. It has been known for a long time that embryonic extracts accelerate the growth of cells *in vitro*, and it was further found that extracts of adult tissue were very effective in this respect—i.e. the substances capable of stimulating cell multiplication *in vitro* are not limited to proliferating tissues but are also present in stable mitotically inactive tissues (Carrel, Walton, Trowell and Willmer, Doljanski and collaborators). Numerous experiments have

been reported on the application of embryonic extracts to experimental wounds in laboratory animals and to indolent wounds in humans (Amorosi, Bergami, Bugliari, Carnot and Terris, Goldberg, Kiaer, Morosov and Striganova, Nakamura, Nielsen, Roulet, Schloss, Wallich, Waugh). In most cases favourable results were claimed.

It was therefore natural to determine by animal experiments whether cell growth-promoting adult tissue extracts can also accelerate the course of wound healing. In 1944 Auerbach and Doljanski (*Brit J exp Path* 1944, 25 38) performed experiments on experimental wounds in rats treated by topical applications of saline heart extracts and alcohol precipitates therefrom, and on the basis of controlled experiments in 92 animals they stated "Extracts of adult hearts when applied locally did not, thus, accelerate the course of healing of treated wounds as compared with control wounds in the same animal, they would even appear to cause a slight inhibition." In 1946 Young, Cruickshank, and Martin (*J Path Bact*, 1946, 58, 63) reported similar results in rabbits.

The above observations do not settle the problem of promoting the wound healing *in vivo* by substances which activate cell multiplication *in vitro*. The possibility must be considered that the locally applied cell growth-promoting extracts do exert an accelerating action on the rate at which the wounds heal. This acceleration, however, could not be perceived from a comparison with control wounds in the same animal, since the healing process in the latter, too, might be hastened by growth-stimulating substances absorbed from the wound surface and entering the circulation. To elucidate the question if the cell-growth-stimulating substances introduced parenterally can affect the process of repair of healthy wounds the following experiments were undertaken (*Proc Soc exp Biol NY* 1945, 58, 111). Thirty rats with experimental skin wounds received intraperitoneal injections of a saline extract of adult chicken heart, the injections being repeated every second day until the wounds closed. The rate of wound healing in animals treated in this way was compared with that of wounds of equal size in untreated rats. The experiment shows that the parenteral treatment with cell-growth-promoting extracts of adult hearts caused a significant reduction (21.8%) in the mean time required for healing as compared with the controls. These findings relate to rats only and are on a small scale but they do indicate that the problem of the action of the cell-growth-promoting tissue extract on the process of normal wound healing is by no means settled and requires more intensive study—I am, etc.,

Jerusalem

L. DOLJANSKI

Adaptation of EMS Huts for Children's Wards

SIR—I was much interested in Dr Wilfrid Gaisford's and Mr C H Elkins's plan for adaptation of EMS huts for children's wards (Dec 7, 1946, p 867). The authors were good enough to refer to the plan for the same purpose prepared by my colleague, Mr Coales and myself and published in the *Monthly Bulletin* of the Ministry of Health (February, 1946) and I was grateful to them for quoting our remarks in favour of different methods of adaptation being explored. There are a great many of these huts in the country, and it is much to be desired that a number of people should exercise their ingenuity in devising different ways of adapting them and should make public the results of their efforts. Requirements differ and plans should differ with them. Stereotyping of hospital design is, above all, to be avoided and, whether adaptation of existing buildings or designing of new buildings is in question, it is by pooling ideas and by experiment and discussion that we shall arrive at the best results.

It may be worth while to say a few words about the chief differences between the Gaisford-Elkins and the *Bulletin* plans. I have been so much struck by the poor quality of most of the hospital accommodation for children throughout the country that, when Mr Coales and I came to the plan for children's wards in our hut adaptation series, we took the opportunity of trying to devise accommodation which should meet the special needs as well as could be done within the rigid framework at our disposal. Accordingly we thought it worth while to produce a rather elaborate plan involving quite a substantial amount of adaptation. Dr Gaisford and Mr Elkins, on the other hand, aimed at showing "how a typical EMS hutted ward may be modified at reasonable

cost and with minimal structural alterations to accommodate infants and children in surroundings where the chances of cross infection are lessened and other desiderata are provided." Both these lines of approach have their value. The essential differences between the two plans seem to me to be:

(1) The *Bulletin* plan provides a sluice room, a bathroom, and sanitary accommodation in a central position, while the Gaisford-Elkins plan has these conveniences at the end of the hut only.

(2) In the Gaisford-Elkins plan the single bed cubicles open into the main ward and are approached only through it, while the *Bulletin* plan contains a series of entirely separate single-bed rooms opening into a corridor.

The advantages (as they seem to me) of the above-mentioned features of the *Bulletin* plan have to be weighed against the undoubted merit of economy in cost, labour, and materials of the Gaisford-Elkins plan. Of the two main points of difference (2) is much the more important. The risk of spread of infection in children's wards is never absent, and my personal opinion is that the *Bulletin* plan gives greater safety in this respect, sufficient to warrant the extra cost and use of labour and materials. Dr Gaisford and Mr Elkins, however, have evidently had in mind circumstances which, in their view, would make the degree of separation shown in their plan sufficient. It would be interesting to learn the opinions of others of your readers on this question—I am, etc.

Ministry of Health

T S McINTOSH

The Filigree Operation for Hernia

SIR—The note upon the filigree operation for hernia by Mr D M Cooper (Feb 1 p 182) is valuable in that it brings into daylight a good method of hernia repair which has been obscured by a multitude of ingenious plastic manoeuvres for closing the inguinal canal. Many of the complications that he details in his paper appear to be hypothetical rather than probable.

Since the technique of Mr Percival Cole was introduced at the Yeatman Hospital, Sherborne, by Dr Richmond McIntosh about 15 years ago almost every inguinal hernia in adults operated upon by himself and by me has been treated by the filigree method. Out of some hundreds of cases I know personally of only one case that has suppurated and one that relapsed; in the latter I did not find it difficult to dissect out the old filigree nor to make a bed for a new one. Post-operative pain has never been more severe than that experienced after the Bassini type of repair. No patients have complained of pain when moving about in bed nor after leaving the hospital. Neither secondary haemorrhage nor faecal fistula has occurred. I am happy to subscribe myself as a humble disciple of Mr Percival Cole—I am, etc.,

Sherborne Dorset

JOHN WHITTINGDALE

Health Service in Rhodesia

SIR—As Director of Medical Services my attention has been drawn to the leading article (Nov 23, 1946, p 777) dealing very impartially with the health services in Rhodesia and more particularly with the recent National Health Commission's report. It is desirable, however, to contradict the last sentence of your article. This reads "the system whereby our voluntary hospitals are staffed by physicians and surgeons who give their services without payment" is quite out of the question in the Rhodesian scene."

On a point of fact for more than twenty years the two larger hospitals in Salisbury and Bulawayo have had staffs of honorary physicians and surgeons who have given their services without payment. Furthermore throughout the war these honorary consultants included in the scope of their work and equally without payment the medical and surgical care of all serving members of the Forces whether Rhodesian or members of the Royal Air Force training in the Colony under the Empire Training Scheme. Several of these consultants each performed hundreds of operations and the numbers of patients seen in consultation passed well into the thousands during the war years alone—I am, etc.,

R M MORRIS
Director of Medical Services

Obituary

ARTHUR WHITFIELD, M.D., F.R.C.P.

British medicine lost an outstanding figure when Arthur Whitfield died at his home in Eastbourne on Jan 31. He was one of the most eminent of the group of physicians who followed Radcliffe Crocker, Tilbury, and Colcott Fox, and who finally established dermatology as a special subject demanding intensive study.

Born in London on Oct 13, 1868, he received his early education at King's College School. After qualifying from King's College Hospital in 1891 he took the London M.B. a year later. During the first three years after qualification he held several appointments at his own hospital, including that of Sambrooke Medical Registrar. He proceeded M.D. in 1893, and was admitted M.R.C.P. in the same year. Then followed a period of study in Berlin and Vienna. In 1896 he was appointed assistant physician at the West London Hospital but his interest in dermatology quickly led him to the Royal Northern Hospital. In 1899 he returned to King's College Hospital as assistant physician to the skin department. Thereafter he devoted his whole energies to the establishment of dermatology as an important specialty. At that time diseases of the skin were usually dealt with by one or other of the general physicians or surgeons of a hospital, a custom which at first led to some disapproval of this innovation. Whitfield also decided that his practice both in private and in hospital must be rigidly restricted to dermatology, no easy decision in those days but one which he deemed essential to the advancement of his subject. The success of these endeavours was seen seven years later when, after two years as Dean of the Medical School, he was appointed Professor of Dermatology in King's College only one year after he had been elected to the Fellowship of the Royal College of Physicians of London. Thereafter, such as that of Medical College,

Elliott & Fry, Ltd.]

but there is no doubt that he gained the greatest pleasure from his work for St Dunstan's. He was elected a Fellow of King's College in 1909, and he was chairman of the Medical Board from 1914 to 1918 and again from 1926 to 1928. Although he suffered for many years from a disabling infirmity, Arthur Whitfield maintained his enthusiasm for work with an unflagging energy which often left him exhausted. For example, during the 1914-18 war he added to his labours by attending the Prince of Wales' Hospital for Officers, by assisting the greatly depleted King's staff as a general physician in charge of out-patients, and by spending his evenings in looking after the general practice of a great friend who had joined the Army. He was president of the Section of Dermatology of the Royal Society of Medicine from 1919-21 and received the unusual honour of election to an Honorary Fellowship of that society only last year. In 1924 he was secretary of the British Association of Dermatology and Syphilology, becoming president in 1927. During this period he received numerous other distinctions. He was Lumleian Lecturer at the Royal College of Physicians in 1921 and was a councillor of that College from 1922 until 1924. The French Society of Dermatology made him a corresponding member an honour which he valued greatly.

While his name is most generally associated with his work on fungous infections, he wrote many articles all of which were distinguished by acuteness of perception, clear reasoning, and a clarity of style which made his contributions to our knowledge outstanding. The same features distinguished his

Handbook of Skin Diseases and Their Treatment. All branches of mycology interested him, and he was one of the pioneers in the use of x rays for treatment of ringworm of the scalp. He published his discovery of the pathogenicity of fungi in *linea pedis* in 1908, thus anticipating Sabouraud by at least two years. Some years after this work had received general confirmation and acceptance he himself discovered that Djellaludin Muktar had made the same suggestion in a small journal about two years before his own work was published. Thereafter he made frequent public acknowledgments of this fact. The ointment which bears his name proved the starting point for all subsequent work along these lines. In later years its efficiency was called into question, largely because his original formula had been forgotten in a welter of modifications. Attention has recently been drawn to this fact in the *British Journal of Dermatology and Syphilology*. The corresponding lotion which he devised is even more valuable, although he left its publication to others. He made important contributions to the study of eczema, of animal parasites, and of dermatitis caloricæ among many other subjects. At the International Congress in Budapest in 1935 he introduced his conception of autophytic eczema, the importance of which in allergic skin manifestations is now generally recognized.

Arthur Whitfield's success was largely the result of the wideness of his interests. No subject was too trivial for consideration, particularly if it concerned an allied science. Always he sought its possible application to medicine. He first used benzoic acid after he had noted its value in dairy work. But behind everything else there was shrewd observation and a hatred of anything suggestive of carelessness. In one of his last letters he insisted on this point: "Always examine your cases thoroughly, thoroughly, thoroughly. Re-examine them. Re-examine your own deductions." Nevertheless he found time for outside interests. As a young man he was a keen lawn tennis player and he played golf though with decreasing frequency, until a year or two ago. His real hobby, however, was his beautiful garden in Beaconsfield, where he spent every weekend working and experimenting. To this he was able to give more time after he had left the active staff of King's in 1927, when he retired at an early age but with the titles of Emeritus Professor and Consulting Physician. He was a physician of deservedly international reputation. Dermatology as a whole owes a very great deal to him, but his past students from all over the Dominions and Colonies, as well as from this country, will always remember him as a man who won their affection and gratitude. In their work his memory lives on as a direct continuation of his precepts and encouragement. To his widow and family we extend our sympathy, a sympathy the more real as we acknowledge the loss of one who himself had extended friendship and help to so many.

Sir Archibald Gray writes: By the death of Arthur Whitfield British dermatology has lost an outstanding and much respected figure. Entering the field of dermatology some fifty years ago when knowledge of the bacteriology and mycology of the skin was in its infancy, Whitfield threw himself with vigour into the study of these subjects. Stimulated by the example of Colcott Fox, whose assistant and devout disciple he was, his work, whether in the clinic or the laboratory was characterized by meticulous attention to detail and by prolonged and careful study of the problem before him. It may not be remembered in these days that the credit of first finding fungus in ringworm of the toes was Whitfield's, and this discovery an epoch making one, was due to his habit of systematically examining scales under the microscope over a period of many years. It is to be hoped that as his name is likely to remain attached to a remedy which he introduced for this condition, and which has stood the test of time it may serve as a reminder that it was he who discovered the cause of the disease. It is not for me to describe here his contributions to dermatology which were many and important nor the various offices which he held but I should like to add a few impressions of the man. His most striking characteristic was that of perpetual youth. Throughout his active professional life he had all the alertness and inquisitiveness of a boy. Everything that he saw whether in his work or outside interested him and he always had to get to the bottom of any problem that he took up. I can remember him at breakfast in a Budapest Hotel discoursing on the varieties of Continental rolls, of which he had a complete knowledge

and on the method of determining the ripeness of peaches. It was my privilege to assist him in one of his clinics a good many years ago. A more stimulating experience it is difficult to imagine, especially as the clinic terminated in a long tram-ride during which he discoursed on every subject under the sun. We all missed him greatly when he retired from active work a few years ago, and now his death will bring sorrow to his many friends.

Dr A C Roxburgh writes: My generation of dermatologists greatly laments the death of Arthur Whitfield, whom we regarded as one of our most valued teachers. Those of us, like myself, who were never officially pupils of his learned much from listening to his remarks at dermatological meetings and especially from conversations with him about cases at such meetings. I saw a good deal of him at the International Dermatological Congress at Copenhagen in 1930 and afterwards in Stockholm, and at the Budapest Congress in 1935, which made these congresses all the more enjoyable. I am grateful to him for much helpful advice and information while I was editor of the *British Journal of Dermatology* and also when I was writing a certain small book on dermatology. He was always accessible and always ready to help with information or references. His fund of information was not confined to dermatology by any means, for he was knowledgeable on food and drink, gardens and dogs, among other subjects. Whitfield did not suffer fools gladly and had very definite views on most subjects, which he was in the habit of stating in a rather dogmatic manner. To younger dermatologists he was always most helpful, and all of us mourn the passing of one of the outstanding figures of a great generation of British dermatologists.

HERBERT H LANKESTER, M D

Herbert Henry Lankester died at Eastbourne on Jan 30, after a short illness. Dr Lankester, who was 84, was a founder and the first secretary of the Medical Mission Auxiliary of the Church Missionary Society. The eldest son of Dr Henry Lankester, of Leicester, he was born on March 20, 1862 and was educated at Tettenhall College, Wolverhampton. A student of St Thomas's Hospital, he took the L S A in 1863, the M R C S a year later, and the London M B in 1885. He proceeded M D in the following year after a period as house-physician and resident accoucheur at St Thomas's. He practised privately in South Kensington for a time before becoming secretary of the Medical Mission Auxiliary in 1891 and he served as secretary of the Medical Missionary Fund and physician to the Church Missionary Society from 1894 to 1903. He was then secretary of the C M S for the next seven years, financial secretary from 1910 to 1923, and finally general secretary for three years after that.

Dr Lankester was the first editor of the C M S magazines *Mercy and Truth* and the *Home Gazette*. He had been one of the representatives of the Diocese of Winchester in the House of Laymen, a member of the Southwark Diocesan Conference, and Diocesan Lay Reader for the Diocese of London. Since its foundation in 1908 he had been a member of the executive committee of the Central Board of Missions. Dr Lankester had been in retirement for about twenty years. He married in 1883 Gertrude, daughter of Col J S W H Farrer, Coldstream Guards, and had one son and two daughters. Mrs Lankester died in 1932.

HARRY EMSLIE SMITH died at his home in Dunfermline, Fife, on Dec 18, 1946. The youngest son of the late Alexander Emslie Smith, he graduated M B, Ch B at Aberdeen in 1900. He held resident appointments at the Great Northern Central Hospital and at Queen Charlotte's Hospital, London, before entering the I M S in 1902. After serving with a number of Indian regiments, he was appointed to various chemical examinerships between 1907 and 1910. During the latter part of this period he was professor of chemistry at the Medical College, Calcutta. Then followed a year as resident surgeon at the Eden Hospital, Calcutta. In 1912 he took the D T M & H at Cambridge and studied ophthalmic and general surgery in Leipzig. On returning to India he held various civil surgeoncies. His civil employment was interrupted by the first world war during the course of which he served in hospital ships, later in India, and from 1918 onwards in Iraq. He retired from the Service in 1923 with the rank of lieutenant-colonel. He had taken the D P H in the same year and he was then appointed lecturer in anatomy at the Dunfermline College of Hygiene

and Physical Education, later becoming administrative medical officer to the Carnegie Dunfermline Trust. He proceeded M D in 1930. During the second world war he was medical superintendent of the Inglis Street E M S hospital while continuing his work for the Carnegie Trust. An enthusiastic amateur musician, he is survived by his widow, two sons, both members of the profession, and one daughter.

VICTOR ROBINSON died in New York City on Jan 15, and the world of medical history has been robbed of one of its most striking figures. Born in the Ukraine on Aug 16, 1886, Victor was taken in infancy to the United States of America, where his father, Dr William J Robinson, became one of the early advocates of birth control. After studying for two years at the New York University Law School, he turned to pharmacy, taking the Ph G at the New York College of Pharmacy in 1910, the Ph C at Columbia in the following year, and the M D at the Chicago College of Medicine and Surgery in 1917. He entered the field of medical history as he had entered several others—out of curiosity. For thirty-eight years Victor Robinson devoted himself with dogged perseverance and unquenchable enthusiasm to the pursuit of this subject, successfully playing the part of author, editor, lecturer, and radio speaker. A prolific facile, and entertaining writer, one of his best-known works is *Pathfinders in Medicine* which appeared as early as 1912. His last book, *Victory over Pain*, was published just before his death. For many years he edited the monthly magazine *Medical Life* at one time the official organ of the American Society of Medical History. Though his fondness for over-dramatization and his almost childish delight in "purple patches" did not appeal to the palate of many historians, they all had to admit that he was always accurate, possessing a scholar's conscience in consulting the original sources. A retiring, sensitive little man, Victor Robinson was a charming and stimulating companion, whose mind seemed most active after midnight. He was appointed professor of the history of medicine at Temple University Medical School, Philadelphia, in 1929 and lecturer on the history of nursing in 1937.—W R B

Dr IAN STEWART MCGREGOR died suddenly at his home on Jan 23 at the age of 43. Ophthalmology has lost one of its most promising and faithful adherents. The first decade of the period since his graduation from the University of Glasgow in 1927 was spent in resident hospital appointments in general medicine and surgery and later in general practice on the Island of Bute. His sure knowledge of medicine, his keen mind and the sympathy which allowed him to assess patients and their problems truly but with charity combined with his catholic tastes in painting and literature to make him an ideal general practitioner esteemed by all. This, however, was but a period for the measurement of his own capacity and for his individual staking of the limits of medical practice. Once sure of these he confined his direct attention to ophthalmology with such zeal and concentration of purpose that within seven years he had become clinical assistant to the Glasgow Eye Infirmary, assistant to the professor of ophthalmology of the University, and visiting surgeon to the Ophthalmic Institution. Within that same brief period he took the M D and the D O M S and was admitted to the Fellowships of the Royal College of Surgeons of Edinburgh and Royal Faculty of Physicians and Surgeons of Glasgow. This despite an absence for several years on war service when he held the rank of squadron-leader in the R A F V R. His rapid acceptance in the highest ranks of his specialty in Glasgow was essentially due to those qualities which had made him so successful in general practice together with the growing evidence of his power of original thought. True to character, his publications awaited his precise knowledge of the known boundaries of ophthalmology, but when they came they had the true marks of developing originality and were a promise of greater things to come. His work on melanotic tumours of the choroid and on certain aspects of neuro-ophthalmology are of lasting value. But to many of us Ian McGregor will continue as the memory of an enchanting if at times unpredictable character. He could quickly sense the ridiculous, which gave him wit, and the unfair which made of him a hard-hitting opponent. Generous in things, thoughts and feelings, he was a true friend and a good companion. Much of his time in recent years was devoted to his widowed mother to whom the sympathy of his friends is extended now in her great loss.—I C M

Dr ERIC JOHN STADDON of Ipswich, Suffolk, died suddenly on Jan 22 at the age of 56. Dr Staddon was still continuing the practice which had been started by his grandfather, the late Dr John H Staddon. Educated at Ipswich School and St Thomas's Hospital, Dr Staddon took the M R C S L R C P in 1913 and was soon afterwards serving in Mesopotamia. In 1919 he returned to Ipswich to join his father in

general practice Dr Staddon was surgeon to the East Suffolk Constabulary, he was a vice-president of the British Legion, and he was well known as a member of the Ipswich Liberal Association. Although his work left him little time for other activities he was an enthusiastic gardener. He had been a member of the British Medical Association for twenty years, and he is survived by a widow and three sons.

Dr BARTHOLOMEW GIDLEY DERRY died at his home in Whinney Hill, Durham, on Jan 24 at the age of 58. His father was for many years prison surgeon at Bodmin, Cornwall. Dr Derry, who qualified in 1917 served in Russia and India during the first world war. He joined the prison service in 1922 and was medical officer at Holloway, at Brixton, and at Dartmoor before succeeding the late Dr R Stuart at Durham. Dr Derry, who had been ill for two or three weeks, was a familiar figure in the Northern Assize Courts, where he frequently gave evidence. He had been a member of the British Medical Association for twenty five years, and he was a warden at St Oswald's Church, and a member of the committee of the Durham Community Service Council.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

The Raymond Horton-Smith Prize for 1945-6 has been awarded to E E Pochin, MD (St John's College) for his paper on "The Mechanism of the Ocular Manifestations in Graves's Disease".

UNIVERSITY OF GLASGOW

At a Graduation Ceremony held on Jan 11 the following medical degrees were conferred:

MD—W T Walker *H Wapshaw *H Wyers G A Macgregor
MB ChB—R A Caldwell Winifred E Cameron J E Carlyle Eileen
Carroll A A Chazan Joan R Christison J I Cohen Anne L Craig K B M

Diplomas in Anaesthetics were granted, jointly with the Royal College of Surgeons of England to the successful candidates whose names were printed in the report of the meeting of the Royal College of Surgeons of England in the *Journal* of Dec 28, 1946 (p 1008). The initials of D S Young were wrongly printed in this report.

Diplomas in Psychological Medicine were granted jointly with the Royal College of Surgeons of England, to the successful candidates whose names were printed in the report of the meeting of the Royal College of Surgeons of England in the *Journal* of Jan 18 (p 121).

Diplomas in Laryngology and Otology were granted, jointly with the Royal College of Surgeons of England, to W F Dickie Clark and to the successful candidates whose names were printed in the report of the meeting of the Royal College of Surgeons of England in the *Journal* of Jan 18 (p 121).

A Diploma in Industrial Health was granted to A L L Silver and a Diploma in Child Health to N F E Burrows, both jointly with the Royal College of Surgeons of England.

Medical Notes in Parliament

SCOTTISH HEALTH SERVICE BILL

The National Health Service (Scotland) Bill was again before the Standing Committee on Scottish Bills on Feb 4.

On a motion that Clause 4 should stand part of the Bill Mr WILLIS said members on the Government side of the Committee desired a definite assurance that the Secretary of State would look into the Clause again. It sought to carry into the new system a feature of the present system which Labour men had always opposed—the setting aside of accommodation for fee-paying patients in hospitals. His Party had fought against the introduction of this into the Edinburgh Royal Infirmary and have fought against it since. In practice the Clause would mean that part of a hospital was set aside for fee-paying patients. If the patient got there some thing which he would not otherwise get this was wrong and if he did not get anything which he would not otherwise get the Clause was a swindle. He suggested that on this point the Bill might with great advantage differ from the English Act.

Mr MCKINLAY said the reason in many cases why people got private accommodation was not because of the nature of their illness but because they had a desire for seclusion and could pay for specialist treatment. He could not understand why the Bill sought to perpetuate the existing system of payment for specialist services. It had been argued that if specialist services were not allowed in private apartments there would be a danger that the specialists would not come near the hospital. He doubted that. There were hospitals in Glasgow which took private patients who paid for the accommodation. He did not think that the patients received better treatment. He had too great an admiration for the medical profession to believe that a specialist's skill was at the disposal of a person only because of the remuneration. In spite of the opposition by the British Medical Association the medical profession was a body of men and women who gave their best to their patients without regard to what might come at the end of it.

Mr GALLACHER said he could not conceive a situation in which any hospital with single rooms would not always have

EFFICIENT Hormone Therapy

Fundamental researches on the
ovarian and testicular hormones
have secured their preparation in
pure, highly concentrated, accurately
standardised forms suitable for
logical and effective use in human
therapeutics. Further, their success-
ful syntheses have made adequate
quantities available at greatly re-
duced prices. British Schering's
complete range of reliable hormone
products worthily reflects these
great advances.

PROGESTIN BDH

Progestin, the natural hormone of the corpus luteum, is of
special importance in the treatment of habitual abortion and
for the control of functional uterine bleeding and menorrhagia.
Ethisterone, a derivative of progestin, has the advantage over
the natural hormone of being active when administered orally.
In certain mild cases Ethisterone BDH may prove to be
effective when administered alone, but it is usually employed
as a means of augmenting the action of Progestin BDH
given by injection. Further details are given in literature
which is available on request.

THE BRITISH DRUG HOUSES LTD LONDON N1

SHor/E/156b

I-SO-GEL, a granular preparation of certain dried
mucilaginous seeds, has the property of reproducing
the normal stimulus to intestinal peristalsis by
increasing the intestinal bulk, through absorption of
water in the alimentary canal.

I-SO-GEL contains no purgatives and is a purely
natural laxative with a smooth mechanical action,
specially suitable for the constipation of diabetes.

It is valuable also in mucous colitis, dysentery,
hemorrhoids, and intestinal flatulence. After the
performance of colostomy, I-so-gel gives excellent
results by solidifying the faeces.

In bottles at 4/6 and 1/5/0 each including Purchase Tax

Vitamin Therapy - its uses and limitations

ACUTE INFECTIONS

A multiple vitamin supplement is a useful basal treatment in febrile conditions when the requirements for the water soluble factors are increased and the diet is usually restricted

Some acute infections, moreover, are commonly associated with low body reserves of certain vitamins. Some also, like pneumonia, provide the uncommon example of urinary excretion of vitamin A, following upon functional hepatic disturbance

For supplying the increased needs of vitamins A, B₁ and C, together with other important nutritional factors, Complevite is recommended for routine use

COMPLEVITE A single supplement for multiple deficiencies

The recommended adult daily dose provides —

vitamin A 4 000 i u	vitamin C 20 mg	iodine	not less
vitamin D 300 i u	calcium 160 mg	manganese	than 10
vitamin B ₁ 0.6 mg	iron 68 mg	copper	p.p.m. each

these rooms in demand on medical grounds. The Clause provided that such accommodation should be available for paying patients only when not needed by any patient on medical grounds.

Criticism of Pay-beds

Mr SCOLLAN said the practice of charging for rooms had grown up over the past twenty-five years. He could remember when in almost any hospital in Glasgow a patient was admitted without any suggestion of his paying for accommodation. The obnoxious practice of fee-paying began when there was grave scarcity of accommodation. A specialist who gave his services to a hospital found ways of getting his patient a bed if he could pay for it. People with serious diseases had to wait eighteen months while others who could afford to go to a specialist got the accommodation.

Mr BUCHANAN said there was strong feeling in the Trade Unions and among Labour members against the Clause, and if he had been sitting elsewhere in the Committee he might have been critical himself. Under the Bill there were no charges at all but a free medical service. If every bed was required Clause 4 would not operate. It was not the issue that somebody outside could say a person should have a bed on medical grounds. The Bill represented a compromise and the Committee had better face that fact. Most of the patients in Stobhill Hospital were now paying.

Mr BUCHANAN said he admitted that the Government would not abolish private nursing homes. These still went on. When the Bill began to work there would be among certain sections of the population a prejudice which if there were no accommodation of the kind contemplated by Clause 4 would drive that type of person into the private nursing home. Some specialists became attached to the nursing home as well as to the public hospital. The Government thought that if it could by this Clause bring that type of person in it would show to people prejudiced against it that the State-run hospital could be as kind and as open handed as any private nursing home. He thought that after some years of this service scarcely anybody would ask for a paid room. It was true that large numbers of poor people who could not pay needed single rooms, sometimes because of nervous trouble. Occasionally there cropped up someone who desired a room of his own for personal reasons. The late Mr Maxton, who entered the Victoria Infirmary, had a single room not on medical grounds but to get a little freedom from interference that was not meant unkindly. The Government made it crystal clear that nobody would be denied a bed. He promised that the Secretary of State would look at the Clause again before the Report stage. In four or five years when the Bill had started work Parliament would have to look at the whole Health Service again because this Bill was not the final word. Parliament could then review the working of this Clause.

Mr CARMICHAEL said the person to decide that the paying patient's case was not so pressing as that of the person who could not pay was the medical administrator. He was not without his prejudices. The medical practitioner or specialist would say he had examined the requirements of both and there was no doubt that one must be admitted, but Labour members knew from experience that the person most likely to be admitted was the man who could pay. The Bill provided little chance of seclusion for the person who was unable to pay. He had to be in a ward with twenty-four other people listening to music and discussing football pools all the time. The future medical service must reduce the size of wards. One of the things which had disturbed working-class people for many years was the differentiation in treatment afforded to people seeking to enter hospitals and after they had entered.

Col ELLIOT said the fundamental point was that it was desirable in the long run that all classes of the community should be served by these great institutions and that there should be no segregation with one section under the State Medical Service and another section going to the private nursing homes. Labour members seemed to desire that the system of private nursing homes should continue. He called that undemocratic.

Need for Privacy

Dr STEPHEN TAYLOR said it was because of the physical nature of hospital buildings that some priority for existing private accommodation had to be worked out in both the English Act and the present Bill. Persons just coming round from serious operations needed privacy as did dying patients. Under the new service they should not allow patients to die in the public ward. He thought most people would be prepared to pay 5s or 10s a week for privacy.

Mr WESTWOOD said that in framing the Clause the Government had been desirous of doing what was best. In view of

the assurance given by Mr Buchanan he asked the Committee to agree to the Clause.

Mr GALLACHER said he had never heard anything so absurd as the suggestion that an Act of Parliament should provide how to decide the use of rooms standing empty in a hospital if they were not needed for medical cases. Mr Herbert Morrison was in a private room of a London hospital. Why should he have to pay? Clause 4 was then ordered to stand part of the Bill.

Charges for Private Patients

Col ELLIOT moved an amendment to Clause 5 to ensure that the charges to be prescribed as payable for patients receiving special accommodation should take account of any revenue from endowments or other sources destined for the up-keep of such accommodation. He said the Bill as it stood proposed that the charge should cover the whole cost of the accommodation. In contrast with the English Act the Scottish Bill proposed that hospitals should retain the revenue from their endowments. Those who were willing to make further endowments might well be attracted by the possibility of providing help for those suffering from some ailment requiring special services.

Mr WESTWOOD said the amendment had been moved without taking Clause 8 into consideration. He would give the Endowments Commission no instructions of any kind except to keep in mind the intention of the donor. He expected the Commission to consider all relevant factors when dealing with endowments.

Mr J S C REID said that as the Bill stood the Commissioner was deprived of a free hand because under Clause 5 it was not permissible to diminish the full cost of the paid block by taking off something provided by the endowments. He agreed that paying wings in large hospitals were generally superior to nursing homes. Therefore such wings should be encouraged. As the middle classes always came off worst in what was called progress it would not be a bad thing that persons should be allowed to assist them if they wished to do so. If the Clause remained as it stood it would be impossible for a charitable donor to say that people in a certain district or people belonging to a certain profession should be assisted in a hospital.

Mr WESTWOOD said this would not be impossible because the Government was trying to safeguard anyone desirous of providing something more than the State provided. There was no legal impediment to his receiving as Secretary of State endowments on the lines now suggested.

The Lord Advocate (Mr G R THOMSON) said he doubted whether there would be any endowments which would cover the situation contemplated under Clause 5. There might be endowments covering the situation contemplated under Clause 4.

Mr REID said at present there were nursing homes not conducted for profit because they were subsidized, and the funds of these would fall automatically under the Bill.

The LORD ADVOCATE said that the existing endowments which would go to the Commission were endowments to wards providing additional amenities and privacy under Clause 4. He was prepared to look into the point which Mr Reid had made about benefactions to alleviate the position of nursing home patients in State hospitals. He recognized that Clause 5 might be read to say that the whole cost of the accommodation had to be charged.

Principle of Equal Treatment

Dr MORGAN said the point was not purely legal but involved a great social change. The whole basis of the principle of equal treatment would be destroyed if some man could leave an endowment in order that certain individuals of a certain class or a profession or a religion should have the right of going into certain wards and if payment were made from the Endowment Fund for the treatment and services given to those people. Did members wish a rich Catholic to give an endowment for an annexe in which only Catholics would be allowed? Or suppose some rich doctor who had made money through exploiting a drug which he had discovered wished to endow an annexe or a ward and keep it generally for the profession. Was that to be allowed under the Bill?

Mrs MANV said that in Norway and Sweden the State hospitals had gradually eliminated nursing homes which had become fifth-rate. All the best surgeons and specialists were in the big hospitals and an ever-increasing flow of the rich took advantage of the State hospitals. Similarly in Scotland patients would gradually flow to the State hospitals. The amendment would bring radiologists' and other equipment to some patients but not to the general ward assuming optimistically that some people would still have some money after this Labour Government had been in office for some years. Medical science had always been for all. Clause 7 laid it down

that the board of management of a hospital should determine how donations should be used but the Clause under discussion enjoined the Secretary of State to have regard to a donor who wanted to throw his money in this direction.

In view of an undertaking given by Mr Buchanan to look into the matter and to meet one of the points concerned Col Elliot withdrew his amendment.

Cmdr GALBRAITH moved an amendment to make applicable to all medical men the provision that the Secretary of State could permit any medical practitioner serving in an honorary or paid capacity on the staff of a hospital to make arrangements for the treatment of private patients of such a practitioner at a particular hospital. He said this widening of the scope of the Clause was necessary in the early stages of the National Health Service. It seemed wrong that a person who was paying for this service and also paying for a doctor of his own should not be allowed to have the service for which he paid through his subscriptions to the National Health Service. It should be possible for him to be admitted to the hospital for which he was contributing and still to be treated by his own doctor notwithstanding that this doctor had not seen fit to enter the Service.

Dr MORGAN remarked that this did not happen now.

Administrative Chaos

Mr WESTWOOD said if the amendment were accepted it would open the hospital to every doctor, including those who were not engaged in the State Service and were hostile to it. This would lead to chaos in administration and he could not accept the amendment.

Mr REID pointed out that a patient was entitled to bring into a hospital in Edinburgh a surgeon not connected with any National Health Service hospital in that city but with a hospital in some other part of Scotland. Yet a doctor who had no connexion with the hospital at all was not entitled to come in in those conditions. Mr Westwood's argument was nonsense.

Dr TAYLOR said there was no register of specialists and the qualification was to be on the staff of some main hospital. The amendment proposed by Cmdr Galbraith was strongly backed by the British Medical Association because that body largely represented the general practitioners, who were at war in a mild way with the specialists who were demanding the right to get into the hospitals because they would then collect a great deal more money. Patients would suffer because part-time surgery done once a week was not good surgery.

Mr THORNTON-KEMSLEY pointed out that the Clause was permissive but not mandatory. If the entry of these doctors into the hospitals would lead to administrative chaos the Secretary of State could prevent it.

Dr MORGAN said that if any general practitioner was on the verge of being a recognized specialist he should get on to the staff of his local hospital. In parts of Great Britain general practitioners were doing excellent work on the staffs of many hospitals and indeed better work than some of the specialists in well-known specialist hospitals. Under the present system it had already been found unworkable to allow any general practitioner to come to a hospital and treat his patient. Dr Taylor had said that this procedure would receive the blessing of the British Medical Association. That was not so. The British Medical Association was anxious that general practitioners should have the right to see their patients in hospital but only in consultation with the visiting surgeons and the staffs and not to treat them except in rural hospitals where a general practitioner had a specialist standing. To give a uniform standard of treatment to patients in hospitals a general practitioner could not be allowed at the wish of his patient to come to the hospital and treat the patient as he liked. Some doctors were in favour of treating cancers by the application of plasters.

The amendment was rejected by 29 to 13.

Ceiling for Plums

Mr REID moved as a further amendment to Clause 5 to leave out from subsection 2 the final section which provided for maximum charges to be made by specialists who were engaged under private arrangements by patients in paying blocks who were prepared to pay the whole of the charges for their treatment, including those of the specialist. He said that on the English Bill a proposal for a similar omission had been rejected and he recognized a certain difficulty in view of the integration of the profession in having different systems in England and Scotland. Nevertheless it was a pity that Parliament should impose a ceiling. The more the medical profession was deprived of plums by being prevented from overcharging the very rich the less opportunity it would have of giving service to others at cheap rates. If there was to be a ceiling in Scotland it should be the same as the English ceiling, which would be high.

Mr WESTWOOD said he would try in the administration and through the Regulations to dovetail with the English Act. He must resist the amendment.

Sir BASIL NEVEN-SPENCE said the provision was a blot on the Bill and was perhaps intended to put a ceiling on the specialists' income or as the thin end of the wedge to establish a whole time salaried specialist service. The Clause referred to specialist service but the definitions in the Bill made no reference to specialists. He suspected that what Mr Westwood had in mind was another class, the consultants. There was a very deep distinction between the consultant as ordinarily understood by members of the profession and the specialist. The Bill put great pressure on both to come into the Service. Why then depress the prospects of these men by the discouraging proviso in Clause 5?

The amendment was negative. On the motion that the Clause stand part of the Bill Mr MCKINLAY said Clause 5 was even more offensive than Clause 4. If Mr Westwood desired to avoid unpleasantness the Labour members of the Committee asked him to look at the Clause to see if it could be made less offensive or be eliminated altogether. There might be a possible justification for the Clause if there were a surplus of accommodation, but there would not be ample hospital accommodation in Scotland during Mr Westwood's lifetime.

Mr WESTWOOD said he was willing to look into the matter before the Report stage. The discussion was then adjourned.

Ideological Healing

Discussion of Clause 5 was resumed on Feb 6. In response to inquiries by Mr GALLACHER and others Mr WESTWOOD repeated his assurance that he would sympathetically reconsider the Clause. He said that together with other clauses dealing with hospitals it was designed to get the best results possible from the working of the new Health Service. The ideal of a Socialist Commonwealth could not be attained now and some of the things in the Bill were a compromise with reality. As a realist he had to face what he knew were the facts. There would be a shortage of consultants and specialists for some time and he desired to get the full benefit of these specialists in working the Service in Scotland. He could not agree to the Clause being dropped at this stage. He must have time to see how, if the Clause were withdrawn, the service he sought to provide would be affected. Even if the Clause remained in the Bill it would not affect the existing accommodation for public patients. It was not a mandatory Clause and did not impose a duty on the Secretary of State.

Mr J S C REID said that if Mr Westwood gave way on this he would wreck the whole of the hospital part of the Bill.

Mr SCOLLAN said there was nothing so foolish as bringing in ideological points of view in regard to the healing of the sick. When one sent for a doctor one did not ask if he was bringing a Socialist cure or a Tory cure. It was not well known that the most influential section of the medical profession stood out for this Clause not only in this Bill but in the English Act. He was not frightened by the argument that the deletion of the Clause would induce a great development of private nursing homes. To set up a well equipped private nursing home to day required a tremendous amount of capital. An obnoxious feature of the Clause was that it did not tell what percentage of the accommodation in any hospital would be set aside. Nor was there any guidance on what was likely to be the charge. In this Clause the Committee was giving a blank cheque.

Mr N MACPHERSON said the one service where differentiation should be made was in the mental hospital service. If for no other reason this Clause would be justifiable because of its effect in the case of mental hospitals. In treating mental conditions it was essential that the patient should be in surroundings to which he was accustomed. How could differentiation be made except by payment?

On a division the Clause was approved by 29 to 2. The minority were Labour members.

Transfer of Voluntary Hospitals

Col ELLIOT moved to alter Clause 6 so that interests and premises forming part of a voluntary hospital should be vested not in the Secretary of State directly but in boards of management constituted under the Secretary of State. He suggested that the discussion should also cover an amendment by Mr Reid to leave out subsection 2 of Clause 6. Col Elliot remarked that local authorities took pride in the ownership of the great undertakings which they administered but did not take the same interest in properties or undertakings which really belonged to someone else. His friends desired the public bodies looking after these hospital properties to develop the same sense of pride and sense of ownership as voluntary hospitals and local authority hospitals had hitherto developed. If the

Secretary of State appointed a committee to run a property which would vest in them the corporate spirit in running such properties would be more enhanced than if the property vested in the Secretary of State, which in practice would mean St. Andrews House.

Mr BUCHANAN said that if the amendment were accepted the structure of the Bill would be destroyed almost at once. If the State maintained the hospitals it must have responsibility for them and could not hand over to a body which was not responsible to the Government. If the amendment were carried the whole of the Bill would have to be remodelled. The State might decide that a hospital had ceased to serve a useful purpose but if its ownership had been handed over the State must continue to pay the whole cost.

Sir JOHN GRAHAM KERR said that only by increasing the powers of what was called local government could they check the downward progress of democracy. He had lived in Glasgow and knew how proud citizens were of the great municipal hospitals for infectious diseases or mental ailments yet it was proposed to take away these treasures of local government.

Mr SOMERVILLE HASTINGS said he was sure the Committee wished the people of the locality to be interested in their hospital. It was good for the workers in the hospital to feel that their work was so appreciated. He thought the hospitals would be just as much appreciated even if they were owned by the Secretary of State and not by a committee of management.

Mr MCKIE said he understood the intention of the Scottish Office was that the boards of management to be set up under the Regional Boards should so far as possible seek to make for continuity and to maintain local connexions and interests.

Mr REID pointed out that in Scotland neither voluntary schools nor local authority schools were vested in the Secretary of State, and yet Mr Buchanan fulfilled admirably his responsibility for maintaining a proper system of education in Scotland.

By 31 votes to 17 the Committee decided that the voluntary hospitals should be vested in the Secretary of State. On the motion of Mr BUCHANAN this was made more definite by adding the words "for Scotland".

Buildings Not Required

Sir BASIL NEVEN SPENCE moved to insert that if it should be found within two years of the date of transfer that the buildings were not required for providing hospital and specialist services they should, where practicable, be handed back to the previous owners free of charge. He said that just before the war the people of Orkney raised £20 000 to extend their hospital buildings. These buildings, which would now go to the State, were really out of date and it was not likely that they would be used as hospitals. The community was anxious that the buildings should revert to the bodies which now governed them so that they might be used for other purposes.

Mr BUCHANAN said he could not accept the amendment but he could give some assurance on the matter. The management committees of the voluntary hospitals ceased when the Government took over the hospitals. Two years afterwards buildings could not be handed back to committees which in the case of the voluntary hospitals would cease to exist. With present building restrictions two years was far too short a time in which to see what was redundant. In any case the management body of a voluntary hospital was never the owner but only the trustee for the people who had raised the money. If the buildings were found to be redundant the Secretary of State, as an ordinary business transaction would give the local authorities the first chance of taking them over. Buying might not be necessary. It might be possible to have an interchange of sites. With regard to voluntary hospitals the Government view was that wherever possible a place which became redundant ought to be fitted into the hospital scheme. If it could not so be fitted it should be used in some other manner for the general welfare of the community.

Mr HENDERSON STEWART said that although a voluntary hospital might cease to function the trust might remain and might have other purposes for which the building concerned would be useful.

Mr THORNTON-KEMSLEY pointed out that under Clause 9 (1) the definition of hospital was extended to include any clinic, dispensary or out-patient department at which treatment by medical or dental practitioners was provided. Under Clause 9 (4) premises were included which were not at present used as a hospital, so were the sites of proposed buildings, war-damaged buildings and sites which had been cleared altogether. Only after the Secretary of State had surveyed the needs and resources of Scotland as a whole and after the Regional Board had looked at all these properties would the Secretary of State be able to see what hospitals were redundant. Members of the Opposition wished to be assured against what happened in Government departments to-day,

when premises which had been requisitioned for one purpose were, on becoming surplus, hawked about among all Government departments and not handed back to the people from whom they had been acquired.

Mr SCOLLAN cited the case of the Royal Alexandra Infirmary in Paisley, which was built by the subscriptions of the people in the town and surrounding districts. If they discovered that they could dispense with that building would be it be returned to the town of Paisley?

Mr BUCHANAN said Yes. The Government would try to use the hospital building for a suitable general local purpose which would in some way commemorate the use to which the building had been put previously. If the local authority was the only body which could take over and run the Paisley Infirmary then they would get it. The Government had considered the position of hospitals in Scotland and found that very few were run by trustees. Most were run by a committee of subscribers and by a number of workpeople who were elected separately. Therefore there were no continuing bodies of the type which Mr Henderson Stewart had suggested. In his view the administrative machine would have the final say. The important thing was to see that the machine worked with humanity and efficiency.

The amendment was withdrawn. Mr Reid then moved to leave out subsection (2). This proposal was defeated by 29 to 18.

Denominational Hospitals

Cmdr GALBRAITH moved to amend subsection 3 to ensure that nothing was taken over unless it was essential to the Service, and also to forbid transfer unless the hospital could be maintained in its existing form. He pointed out that a number of hospitals could be maintained although they were not taken over. These included such institutions as homoeopathic hospitals and denominational hospitals.

Mr BUCHANAN thought that the substitution of "essential" for "required" would make no difference because the matter would be left to the Secretary of State to interpret.

Mr REID said that Mr Buchanan had declared in effect that he would not take over hospitals unless it was essential. There were a number of small hospitals highly regarded by small sections of the community who wished to maintain them for their own purposes and were willing to pay for them. He understood from what Mr Buchanan had said that these hospitals would be able to carry on their duties under private management.

Mr BUCHANAN retorted that he did not say that at all.

Mr REID thought that Mr Buchanan intended to give an assurance to those who ran hospitals which were not essential for the working of the Service but were in the hands of religious or other bodies, strongly supported by a portion of the population and catering for it. He was sure the Committee desired such an assurance to be given.

Mr BUCHANAN said Mr Reid's second statement came closer to the Government's intention. If the Government found that a place was not required or was not essential it would not take it over.

Mr THORNTON-KEMSLEY said there were many institutions—nursing homes if Mr Buchanan chose so to describe them—which were not run for profit but were endowed for certain specific purposes. He asked Mr Buchanan to consider publishing after the Bill became law a list to give some assurance that he did not intend to take over such and such a nursing home.

Mr BUCHANAN said he would look into that suggestion.

Mr HASTINGS thought that very few hospitals would not be required. He hoped the Secretary of State would use every hospital he could and that where its special character could be continued under the scheme that would be done.

Mr MACPHERSON warned Mr Buchanan that if he took over more hospitals in the smaller burghs of Scotland these small burghs would start subscribing to new ones and would insist on having their own show.

Sir THOMAS MOORE said that on the west coast of Scotland a great number of retired nurses had started small nursing homes which were well run. These women were anxious to know whether they would come under the Clause.

Mr BUCHANAN said that a nursing home carried on for profit even a small profit would not come under the Bill. The amendment was then withdrawn.

Mr Reid moved to leave out the words "before the appointed day" from the provision dealing with the Service by the Secretary of State of notice on a governing body or a local authority that a hospital would not be required. He said the appointed day was only a year away and there might not be time to consider all these things. He suggested that Mr Buchanan should agree to leave over such decisions until June or July, 1948. Mr BUCHANAN said he would look at this point.

EPIDEMIOLOGICAL NOTES

Measles in Belfast

The present epidemic of measles began in Belfast at the end of October, 1946, being true to type in this respect. The previous epidemic in 1944-5 was unusual in that it started in early summer. Weekly notifications of first cases in the household, with the corresponding figures for two years ago, are as follows

Week ending	1946-7 Notifications	1944-5 Notifications
Nov 2	32	143
9	23	200
16	43	187
23	47	258
30	106	259
Dec 7	179	264
14	219	245
21	149	245
28	325	178
Jan 4	758	278
11	755	231
18	889	106
25	910	140
Feb 1	760	115
8	739	111

The type of case is of moderate severity, and most of the deaths have been due to bronchopneumonia

Discussion of Table

In *England and Wales* an increase in incidence was recorded for measles 584, scarlet fever 60, cerebrospinal fever 36, and dysentery 25. The only disease which was less prevalent was whooping-cough, with 41 fewer notifications.

The largest rises in the notifications of measles were those in Lancashire 409, Yorkshire West Riding 130, and Middlesex 128, the largest falls occurred in Northumberland 149 and Durham 112. There were only small variations in the local trends of scarlet fever, notably a decrease in incidence of 25 in London and an increase of 23 in Warwickshire. The only change of any size in the notifications of diphtheria was a decrease in Durham 11.

The largest fall in cases of whooping-cough was that of Lancashire 77, and the largest rises were London 38 and Staffordshire 33.

The outbreak of dysentery in Hertfordshire, St Albans R D, flared up again. The notifications for the past three weeks were 24, 5, and 20.

Over half of the counties had a case of cerebrospinal fever, the largest returns being those for London 13, Lancashire & Yorkshire West Riding 7 and Warwickshire 6.

In *Scotland* a decrease was recorded in the incidence of whooping-cough 82, acute primary pneumonia 46, and scarlet fever 22. Notifications of dysentery rose from 17 to 32, the increase being largely due to the experience of Edinburgh, where the cases increased from 5 to 16.

In *Eire* there was a decrease in the incidence of measles 37 and of diphtheria 18.

Sickness Survey

A brief summary of the results obtained by the Social Survey during March to May, 1946, published in the *Monthly Bulletin* of the Ministry of Health and the Public Health Laboratory Service (Jan., 1947, p. 4), shows that a slight increase in the incidence of minor illness has occurred compared with the preceding years. The proportion of people aged 16 to 64 who recalled having suffered from any illness, ailment, or injury during the three months preceding the interview was 33% in February, the highest rate so far recorded. The rate declined to 78% in May and June. In 1945 the proportion fell from 82% in March to 73% in June. The percentage morbidity for serious, moderate, or mild illness ranged from 7.4 in January to 4.0 in May and for minor or ill defined causes from 32.3 in January to 26.6 in March, rising to 31.0 in May. About one out of 12 men and one out of 10 women recorded some complaint included in the group of 'functional digestive disorders'.

Week Ending February 1

The notifications of infectious diseases in England and Wales during the week included scarlet fever 1,135, whooping cough 1,890, diphtheria 176, measles 13,501, acute pneumonia 1,278, cerebrospinal fever 83, acute poliomyelitis 12, dysentery 61, paratyphoid 1, typhoid 6. Deaths from influenza in the 126 great towns numbered 148.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Jan 25.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland.

Figures of Births and Deaths and of Deaths recorded under each infectious disease for (a) The 126 great towns in England (b) London (administrative county) (c) The 13 principal towns in Eire (d) The 10 principal towns in Northern Ireland.

A dash — denotes no cases. A blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland and the returns are therefore an approximation only.

† Includes primary form for England and Wales (London (administrative county) and Northern Ireland).

‡ Includes puerperal fever for England and Wales and Eire. It is still not possible to publish the return of births and deaths for Eire for the weeks ended Oct 26 Nov 2, 9, 16 23, 30 Dec 7, 14, 21, 28 1946 Jan 4 11 18 and 25, 1947.

Medical News

A meeting of the Middlesex County Medical Society will be held at Central Middlesex County Hospital, Park Royal London N.W., on Friday, Feb. 14, at 3 p.m., when there will be clinical demonstrations and a short paper by Dr R. Asher on "The Dangers of Going to Bed."

A meeting of the Medico Legal Society will be held at 26, Portland Place, W., on Thursday, Feb. 27, at 8.15 p.m., when Mr W. Harwood Carlisle will read a paper on "Alleged Manslaughter by Excessive Violence during Coitus."

The Chadwick Trust (204, Abbey House, Westminster, S.W.) announces the following public lectures: Feb. 18, 2.30 p.m., at 26, Portland Place, W., Prof S. P. Bedson, F.R.S., "Laboratory Investigations in the Diagnosis of Virus Infections of Man"; March 18, 5.30 p.m., at Westminster Hospital Medical School, 17, Horseferry Road, S.W., Prof W. M. Frazer, "A Medical Pioneer in Sanitation"; May 22, 3 p.m., at Cheltenham Town Hall, Sir Arthur MacNalty, "Advances in Preventive Medicine during the War of 1939-45." Admission to the lectures is free and no tickets are required.

The annual meeting of the Court of Governors of the London School of Hygiene and Tropical Medicine (Keppel Street, Gower Street, W.C.) will be held on Wednesday, Feb. 19, at 5 p.m.

A series of lectures will be given at the Royal Institute of Public Health and Hygiene (28, Portland Place, London, W.) on Wednesdays, at 3.30 p.m., from Feb. 19 to March 26, both dates inclusive. Admission is free, without ticket. Details will be published in the diary column of the Supplement.

The following radiological meetings will be held in London this month: Thursday, Feb. 20, 8 p.m., British Institute of Radiology, 12, Welbeck Street, W., discussion on "Radiation Necrosis" to be opened by Mr A. H. McIndoe, Dr R. Forbes and Mr G. F. Stebbing; Friday, Feb. 21, 2.30 p.m., Therapy Section of Faculty of Radiologists at the Royal College of Surgeons of England, Lincoln's Inn Fields, W.C., paper by Dr L. H. Gray and Mr B. J. Banfield, "An Optical Apparatus for Dose Exploration in Multiple Field Technique"; Friday, Feb. 21, 8 p.m., Section of Radiology of Royal Society of Medicine, 1, Wimpole Street, W., discussion on "Carcinoma of the Thyroid" to be opened by Mr J. M. Graham and Dr R. McWhirter.

The next quarterly meeting of the Royal Medico Psychological Association will be held at 11, Chandos Street, London, W., on Friday, Feb. 21, when the proceedings will open with a business meeting at 10.15 a.m. At 11.30 a.m., papers on "Psychiatry and the Population Problem" and "A Survey of Subnormal Types" will be read by Dr C. P. Blacker and Mr R. Caradoc Jones respectively. At 2.15 p.m. Dr J. A. Fraser Roberts will read a paper on "High Grade Mental Deficiency in Relation to Differential Fertility." Members who wish to attend the May meeting of the Association at Gloucester and/or the annual meeting at Eastbourne are advised to communicate with the secretary at 11, Chandos Street, W.1, as accommodation is limited.

To celebrate the centenary of the Chemical Society Sir Harold Hartley, F.R.S., will deliver a commemorative address entitled "A Century of Chemistry" before the Royal Society of Arts and the Chemical Society at 8, John Adam Street, Adelphi, London, W.C., on Wednesday, Feb. 19, at 5 p.m.

The second International Congress of the International Academy of Legal and Social Medicine will be held at Brussels and Liège from June 25 to 28 and will be divided into five sections: legal medicine in its application to crime, social medicine, industrial medicine, medico legal and social psychiatry and scientific police methods. The languages will be English and French. Those who wish to present reports or read papers should notify without delay the president of the Congress Prof Dr M. De Laet, Faculté de Médecine 7, Rue de la Gendarmerie, Brussels or one of the general secretaries Prof Dr P. Moureau (47 Rue Villedieu, Liège) or Prof Dr F. Thomas (23 Kluyskensstraat, Ghent).

The Ministry of Health has recently issued the *Mental Nurses Subcommittee Notes No. 8* (H.M. Stationery Office 2d). It includes recommendations for revised salary scales of state registered nurses and state certified midwives taking mental training; matron of a training hospital with fewer than 330 beds; temporary (war emergency) nurses; observation ward nurses; and ex-Service male student mental nurses.

An aeroplane carrying a ton of anti-plague vaccine to China left London airport on Feb. 5. It flew westwards, picking up more vaccine in New York.

Dr Ernest Wardlaw Milne, of New Barnet, Herts., who died on Aug. 4 19-6 aged 70, left £23,749. Dr Rodenck Martin Fraser, of Somerset, who died on Oct. 8, 1946, left £9,476.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Dermatitis Herpetiformis

Q—Is there any satisfactory treatment for dermatitis herpetiformis? A male patient aged 60 has suffered from it for six years. Quinine, arsenic purgatives, and intestinal disinfectants orally, arsenic intravenously, bismuth intramuscularly, high colonic lavages, ultra-violet therapy and numerous applications locally have all been tried without success. The patient is steadily getting worse.

A—Dermatitis herpetiformis may be due to a virus or to some other, as yet undiscovered, cause, and in this sense there is no specific treatment. However, in spite of a certain natural periodicity in the waxing and waning of signs and symptoms this affection is without question considerably influenced by variations in constitutional health and tone, especially emotional tone. Attention should therefore be paid to this aspect of the problem, adjustment to life should be as good as possible, work should not be too laborious or fatiguing, nervous anxiety stresses, and strains should be avoided. A prolonged care-free holiday may do much good.

There are a number of measures which will give temporary periods of relief. Sulphapyridine (0.5 g t.d.s.) has a dramatic effect, and provided precautions are taken against renal irritation and a watch is kept for toxic effects it can be continued over long periods. Pyrexial shock therapy generally gives more or less relief for six months or more. Suramin (B.P.) 0.5 to 1 g intravenously, weekly, for a course of six injections is often effective. Iodides must be avoided, bromides may aggravate the trouble, but phenobarbitone may be employed. At the age of 60 it is important to be sure that the affection is not pemphigus. The transition from dermatitis herpetiformis to pemphigus is not uncommon in the elderly.

Shrinkage of the Gums

Q—I have come across many individuals who although they have perfectly healthy teeth, manifest a definite shrinkage of the gums exposing parts of the necks of the teeth. This exposure makes the tooth extremely sensitive to temperature changes. Is there any treatment which would encourage the growth of the gums?

A—There is, unfortunately, no treatment which will make the gum tissue become reattached to the tooth once this attachment has been lost. The cementoblasts lie on the outside of the cementum and when the gingival attachment recedes the cementoblasts die. The exposed cementum therefore becomes non-vital and the living gingival tissues cannot become reattached. Emphasis should be placed on halting the condition at whatever stage it has reached since the original attachment cannot be restored.

Hyperhidrosis

Q—(i) A patient perfectly fit physically though perhaps somewhat overworked complains of excessive sweating in the axillae. (ii) Several patients complain of excessive sweating (a) in hot weather or in any hot surroundings, (b) after violent exercise, and (c) at night while in bed or at a dance. These patients are healthy men of the athletic type. Is there any treatment?

A—(i) Axillary sweating is emotional in origin, and the essential investigation and treatment must be along psychological lines. Symptomatic treatment may include phenobarbitone 1/4 gr (16 mg) b.d. and belladonna. Locally astringent lotions such as aluminum acetate (2-4%) or sodium hexametaphosphate (10%) or if malodorous, sodium bicarbonate (25%) are recommended. Fractional doses of x-ray through 1/2-1 mm aluminium filter are sometimes helpful but must be employed with caution under the direction

dermatologist (ii) Though aggravated by heat and exercise, the excessive sweating in these cases is dependent upon emotional instability as in the axillary cases. Treatment is along the same lines except that greater reliance must be placed upon the general approach and internal treatment. The following dusting powder on hands, feet, and flexures after bathing may be advised:

B

Sod. hexametaphosphate	5%
Acid. salicyl	2%
Zinc oxide	
Talc	
Acid. bor	aa ad 100
Make a powder	

Adiposity in Young Boy

Q—A boy aged 9 weighs 9 st 2 lb (58 kg) and has a waist measurement of 39 in (99 cm) which is rapidly increasing. I would be glad of any suggestions for treatment.

A—There is not sufficient evidence in this case to make a diagnosis more specific than simple adiposity. This may be constitutional and familial or it may be associated with infantile genitalis, in which case a diagnosis of Fröhlich's syndrome would come into question. This disorder, however, is much rarer than is generally supposed. The adiposity might also follow a hypothalamic lesion, and it is not generally realized that this may be present after encephalitis (often unrecognized) occurring during the course of one of the specific fevers—e.g., scarlet fever or measles. The treatment is that of adiposity in general—namely, diet, thyroid, and diuretics. There is no specific hormone therapy for adiposity.

Mandelic Acid Treatment

Q—Is mandelic acid likely to produce any ill effect if taken indefinitely for the control of chronic *Bact. coli* infection (prostatic)? Sulphonamides are as efficient but there is a relapse of acute symptoms from seven to ten days after stopping either drug. Any advice as regards further treatment would be acceptable.

A—So long as this patient has a focus in his prostate he is liable to recurrences of urinary infection. Treatment in the form of prostatic massage and possibly rectal diathermy should therefore be persisted in. If attacks are associated with renal symptoms intravenous pyelography should also be carried out. Mandelic acid will not have any ill effects provided that renal function is good. The chief objection to mandelic acid treatment in cases of impaired renal function is that it is associated with a reduced intake of fluid, and with a risk of uraemia in the more serious cases. It would seem that this risk is very small in the present case.

Partially Adherent Prepuce

Q—A boy aged 4 months has the prepuce firmly adherent to the under surface of the glans. There is no phimosis and the foreskin pushes right back quite easily on the dorsum and laterally. The mother is anxious to have the boy circumcised. Is this necessary?

A—It is not necessary to circumcise this child. In course of time the prepuce will become less adherent if the mother applies occasionally a little cream and gently massages it back. It is unlikely that anything further will have to be done, and in any case it should not be done now.

Penicillin Treatment of Gonorrhoea

Q—In treating gonorrhoea by a single massive dose of penicillin what is the usual amount given and is it advisable to repeat it in two or three days? I have to treat a man, aged 35, suffering from gonorrhoea of four weeks duration whose condition has not responded to a full course of sulphonamides.

A—A single injection of 200,000 Oxford units of penicillin in oil-beeswax, as supplied by several leading chemists, should effect the cure of gonorrhoea in something like 95 cases out

of 100. It is rarely necessary to repeat the dose and then only if the discharge persists for more than a few days and gonococci can still be demonstrated. The usual tests of cure should be carried out for three weeks at least, and a blood test for syphilis done at three months and again at six months to exclude a possible double infection.

Sebaceous Cysts

Q—A man of 25 is suffering from multiple sebaceous cysts of the neck. Some of the cysts were excised but the majority had to be incised and drained. Otherwise the patient is healthy, has no seborrhoeic condition of the skin or scalp and no local irritation by clothing. Apart from surgical treatment a skin specialist suggested penicillin. The patient received 360,000 units parenterally and the local application of penicillin cream, sulphathiazole ointment and coal-tar ointment with no effect. Would a course of staphylococcus vaccine prevent the sepsis or would x-ray treatment be advisable to prevent the recurrence of the cysts?

A—Sebaceous cysts are naevoid in origin, and only surgical removal is effective. All other measures mentioned in the question are valueless. The ideal method of treatment is to make a wide horseshoe incision and reflect the skin removing the cysts intact from the under-surface. Previous incision and drainage in this case will make the procedure difficult.

Intravenous Novocain

Q—What is the action of novocain when given intravenously?

A—Novocain is a proprietary name for procaine. When procaine is given intravenously it has an action on the heart like that of quinidine and an action on the intestine like that of atropine. It is said to have an analgesic effect also. The Russians are reported to use it in wounded soldiers as we would use morphine. There are no records of a suitable dose for intravenous injection, but the B.P. dose for subcutaneous injection is up to 1 g.

"Dilantin" (Phenytoin) in Epilepsy

Q—A drug called dilantin discovered in 1937 in America is said to be almost a specific in epilepsy—one American book saying '70% of epileptics remain free from seizures so long as they take their daily capsule. Is this drug used in this country and with what results?

A—Dilantin is widely used in this country. Its chemical name is sodium diphenylhydantoinate. Its official name is phenytoin, and it is sold by Boots under the name of "eptoio" and by Glaxo Laboratories under the name of "solantoio". It is used with good results, comparable to those obtained with phenobarbitone or phemitone, which are the official names for "luminal" and "prominal". Merritt and Putnam, who introduced phenytoin, say that in 142 patients with frequent convulsive seizures not relieved by other modes of therapy, phenytoin in doses of from 0.2 to 0.6 g daily for 2 to 11 months gave relief from grand mal attacks in 58%, greatly decreased frequency in a further 27%, and relief from petit mal attacks in 35%, with a greatly decreased frequency in a further 49%.

Treatment of Acne

Q—What is the most recent treatment for acne in a lady of 30? Is there any permanent cure? What advice should be given with regard to diet, cleansing and particularly cosmetics?

A—The "most recent treatment" and "permanent cure" are not terms which easily apply to an affection so essentially constitutional and diathetic as acne. Causative influences are endocrine, psychological, metabolic etc. The question does not admit of an answer. It is not stated whether the lady is single or married. In single women the condition is uncommon in married women almost unknown. It would be advisable to consult a dermatologist. In acne diet should generally be of the "antiretentional" type, cleansing is by soap and water and good cosmetics are harmless.

Letters and Notes

Nocturnal Diuresis

Dr S D STURTON (Streatham) writes I was interested in Mr Bernard Read's experiences, in "Civil Assembly Camps" at Haiphong (Jan 25, p 168). His experiences are not in keeping with my own. I was in Haiphong Road Camp, about five miles away from Dr Read, and our camp was jointly run by the Japanese 'Gestapo' and Army for so called 'political prisoners,' but I noticed that the frequency of nocturnal diuresis varied greatly with the diet. My own camp bed was by a door through which about 10 others used to pass in the dark on their way to the urinal, so I had good cause to be observant. There appeared to be much greater frequency on the nights when we had rice as compared with the nights we had beans or other food. There also appeared to be a greater frequency in this camp than when we were moved to Fengtai Camp, near Peking, where we received millet and brush wheat but no rice, although conditions were otherwise much worse in the latter camp. Other factors against getting up to urinate at Fengtai were the dry heat as against the damp of Shanghai and the fact that it was about a quarter of a mile walk to the latrines and back from some parts of the camp.

Artificial Sunlight in Industry

Dr L SCHMIDT (Linby, Notts) writes In the *Journal* of June 8, 1946 (p 890), you were good enough to publish my remarks concerning Dr Colebrook's report on artificial sunlight. These preliminary remarks were based entirely on my own previous experiments. At the time I promised to expose in detail certain failures and shortcomings of Dr Colebrook's paper in a later publication. May I, therefore, encroach again on the hospitality of your columns to inform those interested that the above pledge has been fulfilled. In an article in the November-December issue of the *British Journal for Physical Medicine and Industrial Hygiene* I have detailed and augmented my previous criticism. On this occasion may I again draw attention to the fact that the colliery clinic at Kirkby, Notts, where I have carried out my latest investigations is not identical with the colliery clinic at Kirkby, Yorks, where Dr Colebrook conducted her experiment. It appears that this fact cannot be emphasized sufficiently. Communications received from colleagues and also interested non medicals, including a leading member of the National Coal Board, show that an erroneous impression still prevails in this respect.

Precautions against Measles

Dr PERCY TATCHELL (London SW) writes In the *Journal* of Jan 11 (p 77) a question was put, what should be done to a child of 18 months in a village full of measles, to guard it against infection? The answer given omitted to point out the desirability of regularly freeing the child's nostrils of mucus—which could be conveniently done by a swab dipped in warm boracic lotion. Since writing last June suggesting the importance of keeping the nostrils scrupulously clean (this I do with soapy fingers daily) as a means of preventing colds, I have been trying my best to catch cold and have completely failed. According to modern investigation infection entering by the mouth can possibly be dealt with by the saliva, which has recently been shown to be a powerful antibiotic but the nostrils are a kind of backwater, with invariably some half-dried mucus *in situ* in the neighbourhood of which infection can lodge and mature. Should this simple expedient prove to be effective against colds why should it not also intercept and abort all airborne infections?

Underground Rooms

Under Section 53 of the Factories Act, 1937, the occupier of an underground room who proposes to use it as a factory workroom must send a notice to the District Inspector of Factories, with prescribed particulars if the room was not so used on July 1 1938. A room used only for storage is not a workroom and 'underground room' is defined as "any room which or any part of which is so situated that half or more than half of the whole height thereof, measured from the floor to the ceiling is below the surface of the footway of the adjoining street or of the ground adjoining or nearest to the room." The necessary form (Factory Form 1229) may be obtained from H.M. Stationery Office or through any bookseller price 1d. Addresses of the District Inspectors of Factories can usually be found in local telephone directories or may be obtained from Local Offices of the Ministry of Labour and National Service.

Age and Intelligence

Dr GUY NEELY (Blackheath) writes A year ago a certain young man passed the Final Fellowship. His father then aged 63 an ex-G.P. and at the time a major in the R.A.M.C., proud yet disconcerted, told me that he could not let his son "get away with

it and would start to read for the Primary. Within twelve months he is a F.R.C.S. Eng. The only coaching he had was from his son, whom he describes as "quite good", the only reading he did was in the evening or late afternoon, after the day's work. He describes the Primary as a "difficult exam" and the Final as comparatively easy. Has there ever been a Commander Gould on medicine? If so, can you supply details? To me this is such an incredible feat accomplished with such quiet dignity and detachment that I can think of no precedent in the whole story of medicine.

Notice to Ships' Surgeons

A circular from the Ministry of Transport draws the attention of ships' surgeons to the importance of consulting the Merchant Shipping Medical Scales before prescribing medical treatment in response to a wireless call received from a British ship with no surgeon on board. The scales prescribed for such vessels are not included in the latest edition of the *Ship Captain's Medical Guide* but must be carried on every ship required to carry a surgeon as well as on other ships. Ships' surgeons can, therefore, see what drugs, etc., are likely to be available for the treatment of the patient for whom they are asked to prescribe.

Too Much Ephedrine

J B I writes While in a chemist's shop recently I was surprised to hear a lady ask for 200 ephedrine tablets 1 gr (65 mg). Questioning elicited that her husband, a sufferer from asthma took eight tablets as a dose, and that the quantity ordered might last a week. The lady stated that she had observed no ill effects from this drastic treatment, and added hopefully that the patient was going back to sea next week and was completely free from the complaint while voyaging. It would seem that further restriction might be placed on this potent drug if self-medication of this nature is commonly practised.

Cheirpompholyx

Dr H C De PENNING (Portsmouth) writes Regarding the severe case of cheirpompholyx referred to under "Any Questions" in the *Journal* (Jan 18, p 123), I have found the following treatment effective. Avoidance of soap and water and the use of a 20% emulsion of benzyl benzoate morning and night. Where patients were compelled to use soap and water, such as housewives who do their own washing of dishes I advise using the emulsion immediately after the use of soap and water, first carefully drying their hands. There were no clinical signs of scabies in these cases.

Treatment of Prapism

Dr A E CARLSBERG (Parkstone, Dorset) writes Referring to the inquiry under "Any Questions" (Jan 11, p 78) on the treatment of prapism, I suggest that before adopting any severe treatment a trial should be given to 5 gr (0.32-g) doses of potassium iodide 3 or 4 times daily. This appeared to be effective within 24 hours after having tried various other remedies, in a case I had twenty years ago. I searched the *British Medical Journal* for many years back before finding this suggestion.

Shadows Under the Eyes

Dr BERNARD SWEETMAN (London, NW 11) writes Excluding individuals suffering from gross organic disease what are the causes of 'shadows' under the eyes seen in apparently healthy people? On close examination enlarged veins may sometimes be seen beneath the lower eyelid. What is the physiological basis for this?

Corrections

Dr T R AYNLEY (Bournemouth) writes In my letter (Feb 1 p 194) the word "back-out" should read 'lock-out'. The words 'British hospitals' should read 'British Hospitals Association'.

In the obituary notice of Dr R V de Acton Redwood (Feb 8 p 236) it was wrongly stated that "Dr Redwood married a Yorkshire lady a Miss North." Mrs Redwood to whom our apologies are due, was formerly Miss Masters of Doncaster.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE EUSTON 2111. Meetings of Branches and Divisions

LINCOLN DIVISION

A general meeting of the Division to which all practitioners in the area were invited, was held at Lincoln on Jan 21, with Dr W. V. Semple in the chair. Thirty-one members were present.

Copies were circulated of a letter from the secretary of the County Hospital in reply to representations made to him that practitioners should be able to refer patients direct to special departments at the hospital for x-ray, pathological, and other examinations without their first being seen by a member of the hospital staff. The gist of the letter was that the E.P.S. laboratory was open to any practitioner for pathological examinations, but a small charge was made for them. With regard to the x-ray department, however, the suggested procedure used to be in force at the hospital, but had had to be abandoned owing to the extra work involved. It was not practicable to reintroduce the system.

The chairman then opened a discussion on the amended recommendation which the Council was to submit for approval by the Representative Body, and he gave a synopsis of the Minister of Health's reply to the letter from the Presidents of the Royal Colleges. A brisk discussion ensued in which Drs Maiden, Morey, Sharrard, O'Brien, Ritter, Lillicrap, A. H. Briggs, Maclure, Fennell and Wray took part. Some speakers felt that, by maintaining a firm attitude and refusing to negotiate further concessions might be obtained from the Minister, but the majority supported the resolution laying emphasis on the phrase "the possibility that discussions may lead to further legislation is not excluded". Dr Sharrard proposed that our representative support the recommendation, and this was seconded by Dr Maclure. Dr Fennell proposed that no negotiations be entered into, and this was seconded by Dr Campbell. On a show of hands Dr Sharrard's proposal was carried by 26 votes to 1.

Dr Fraser drew attention to the ineffectiveness of the B.M.A. public relations and wanted some resolution submitted on this subject. After discussion in which Drs Wray, Hadley, Sharrard, Maiden, O'Brien, and A. H. Briggs took part, no resolution was put forward.

SUNDERLAND DIVISION

The third meeting in the scientific programme was held at the Royal Infirmary, Sunderland on Jan 31. A clinical demonstration was given by Dr G. S. Robinson and Mr W. Grant Waugh and in address was given by Prof. A. A. Moncrieff on "Diseases of the Newborn".

Prof. Moncrieff stated that more children died at birth than were lost through accidents on the road under the age of 12 years. He described the treatment of those conditions which must be recognized and dealt with if the birth rate was to be maintained and preventable deaths avoided. He also indicated the need for an extension of antenatal care.

POSTGRADUATE NEWS

Two weeks' general refresher courses for general practitioners will be held at the Soham General Hospital beginning on March 3, and at Cambridge, from March 17. The fee for the first week is £6d, but one week of either course may be attended at a fee of £4 4s. Schemes of financial assistance are available under which the fee and travelling and subsistence allowances will be repaid, subject to certain conditions to (a) demobilized general practitioners within one year of release from H.M. Forces, (b) doctors engaged in practice under the National Health Insurance Acts. Applications for schedules places in the course, and particulars of the financial assistance available should be made to the Dean of Postgraduate Medical Studies, Trinity Hall, Cambridge, and not to the hospital.

Y CANDLE-LIGHT. This, the smallest B.M.J. since 1840, has been printed on hand-operated duplicators in B.M.A. House, by permission of the Ministry of Fuel and Power and the C.O.I. Our "printer" this week is the Secretary of the B.M.A.

News and views in this issue are evaporated to dryness. Abbreviations will, we hope, be unambiguous.

Distribution of doctors in Britain is done largely through Journal advertisements. Hospital and municipal vacancies are noted overleaf. Candidates should apply to the authorities for details. Changes of 2,000 addresses are held up, and addresses of numerous new members cannot be recorded.

ICAL AND MEDICINE. Shivering, we tend to think of coal only as fuel. Coal is medicine as well. RUNGE discovered in 1834 carbolic acid, a coal-tar product. With carbolic LISTER stoked the fires of surgery for posterity. PERKIN's discovery of the aniline dye mauve in 1856 was the starting point of modern medicine. WEIGERT in 1871 stained bacteria with the aniline dyes of coal-tar, and KOCH soon followed suit. EHRlich hit upon the idea that certain cells had chemical affinity for certain dyes. This led to differential staining of tissues and the birth of chemotherapy. The red dye-stuff protosil patented in 1932, began a revolution in medical treatment - with the

WATER AND SALT DEPLETION*

BY

H L MARRIOTT, CBE, MD, FRCP

Physician with Charge of Out-patients Middlesex Hospital

Causation of Pure Salt Depletion

It has already been explained that the chief effect of salt depletion is a state of secondary or extracellular dehydration consequent upon loss of osmotic pressure in the extracellular fluid therefore to speak of 'pure' salt depletion may seem paradoxical. The expression is meant in a *causal* sense—that is to say the state which occurs in patients who become deficient in sodium and chlorine while being liberally supplied with water. This state is common in medical and surgical practice, but is often unrecognized for what it is. The two essentials for its causation are (1) Abnormal losses of sodium and chlorine. Simple inadequacy of intake does not, as in the case of water, produce serious deficiency. However, low intake or lack of intake may play an important part in the rapid development of depletion when abnormal salt losses are occurring. (2) Adequate water intake. As mentioned earlier, the condition of adequate water intake is frequently fulfilled in these days of dehydration consciousness, when so many patients are rightly put on fluid balance charts. Water is pressed upon them or isotonic glucose solution is parenterally administered. The intake and output figures may be gratifying till the late stages. Yet the patients become weaker and weaker and finally die. Abnormal losses of sodium and chlorine may occur in alimentary secretions, sweat, or urine (Addison's disease). Table IV gives approximate maximum daily losses

and surgical conditions causing vomiting and diarrhoea need not here be enumerated. Acute poisoning may cause extremely violent vomiting and diarrhoea, with precipitous decline of extracellular electrolytes, and provides particularly striking examples of the development of extracellular dehydration within a space of minutes or an hour or two (Marriott, 1935). Reference to Fig 8 shows that vomiting and diarrhoea respectively

cause very different proportional losses of chlorine and sodium. Vomiting causes great relative depletion of chlorine ions and the well-known tendency to alkalosis. Diarrhoea, on the other hand, has the reverse effect, with disproportionate loss of sodium and tendency to acidosis. Therapeutic continuous aspiration of gastric or intestinal contents

(Wangenstein, 1942) can cause great withdrawal of these ions. Lyall and Nicol (1939a and b) found that continuous gastric aspiration resulted in removal of 93 g of chloride expressed as NaCl, in six days. Such an amount represents more than half the body's total. Bartlett *et al* (1938) produced severe salt depletion in normal subjects. Gastric or intestinal suction drainage is a valuable method of treatment, but if used without parallel administration of saline can be highly dangerous.

The effects of pure salt depletion are perhaps best seen in severe sweating, accompanied by free drinking of unsalted liquid, because the relative proportions, though not the concentration, of sodium and chlorine in sweat do not deviate very much from the proportions in extracellular fluid and because there is little loss of other substances. Also, climatic and industrial conditions may permit mass observation of large numbers of normal individuals, suffering only from the effects of salt loss from sweating without obscuring effects due to some underlying pathological condition. Such little understanding as I have of the effects of pure salt depletion comes mainly from observation, during four years in the Tropics, of men sweating severely while drinking water freely (Marriott, 1943, 1945a) supplemented by reference to the experience of others—notably Marsh (1937) whom I visited at Abadan in the Persian Gulf, in 1942. Moss (1923), Dill (1938), Caplan (1942), Taylor *et al* (1943), Ladell Waterlow, and Hudson (1944) and last but not least McCance's classical experimental studies (1936). It was my duty in India to do special tours in the hottest weather (June) to observe heat effects in such particularly

FIG 8—Showing the relative ratio of loss of sodium and chlorine in vomiting and diarrhoea

TABLE IV—Possible Secretion Losses (24 hours)

Secretion	Circumstances of Abnormal Loss	Volume	NaCl Equivalence		
			NaCl	Isotonic Saline	
				Litres	Pints
Sweat	Sweating	ml	g		
		14,000	35	4	7
		1,500	8	1	2
		2,500	18	2	3½
Gastric secretion	Fistula	500	4	½	1
		700	6	¾	1½
Intestinal secretion	Diarrhoea	1,000	22	2½	4½
		7,000	50	6	10½
Urine	Normal secretion	6,000	30	3½	6
		7,000	35	4	7

of sweat and alimentary secretions. It is obvious that prolonged over days or weeks can also cause depletion, particularly if salt intake is lowered. In the case of vomiting and diarrhoea are the commonest causes of abnormal losses of sodium and chlorine. The following table gives approximate maximum daily losses

* If the Clinical Lectures delivered at the Royal College of Physicians on Dec. 2 and 3, 1946. The first part of the lecture of Feb. 1947, page 235.

hot stations as Allahabad, Cawnpore, Lucknow, and Bareilly. The tour of 1942 was particularly instructive, because it happened to be an unusually hot season (maximum shade temperatures in the above stations were between 115° and 123° F (46° and 50.6° C) and sun temperatures very much higher) and because in that year—the first real war year for India—there was not adequate shade provision for men, nor was there general realization of the importance of extra salt intake. During this hot season there were 1,959 admissions to hospital for heat effects and 136 deaths. I personally saw some 400 cases. During my period in the Tropics I also saw salt depletion complicating the picture in many illnesses—for example, scrub typhus (Marriott, 1945b).

Much will be said below about the clinical and pathological features of pure salt depletion as seen, in uncomplicated form, in individuals whose salt loss arises from sweating due to heat. I wish to emphasize that the same clinical and pathological picture is frequently to be seen in the medical and surgical wards of our own hospitals in cases of vomiting, gastric or intestinal suction drainage, biliary or intestinal fistulae, diarrhoea (e.g., ulcerative colitis), and Addison's disease.

The main mechanisms by which the body may be most seriously injured by hot atmospheric conditions are (1) loss of water and salt from sweating, (2) overheating from cessation of sweating. The first is called "heat exhaustion"—an unfortunate term, because it implies mere fatigue whereas it is a serious and may be a fatal state. In 1942 the incidence of this condition in India was 1,405 cases with 27 deaths in British troops and 255 cases with 13 deaths in Indian troops. There were many more Indian troops in the area at the time, and so the incidence in British troops was perhaps thirty to fifty times greater. The probable explanation would seem to be a lower concentration of NaCl in the sweat of Indians. Overheating from cessation of sweating is called "heat hyperpyrexia" or "heat-stroke," and its essential characteristic is a temperature of 107° F (41.7° C) or above. Its underlying cause seems most commonly to be some infection, often minor, which sets off the pyrexia reaction with its associated inhibition of heat-loss mechanism. In India in 1942 its incidence was 170 cases with 34 deaths in British troops and 129 cases with 62 deaths in Indian troops.

Heat hyperpyrexia is not relevant to the present discussion and will not be further considered. Heat exhaustion—heat exhaustion Type 1 in Ladell, Waterlow, and Hudson's classification (1944)—however, when occurring in men drinking water freely, presents a typical picture of pure salt depletion. Sweating without water drinking produces effects mainly of water loss, because sweat is much more dilute than extracellular fluid. Hence in men lost in deserts, and without water, the effects of water depletion overshadow the effects of salt depletion.

Effects of Pure Salt Depletion

Serious depletion of sodium and chlorine gives rise to the following conditions:

(A) An *invariable* loss of total osmotic pressure of the extracellular fluid. In consequence the kidneys excrete water and there is diminution of extracellular fluid volume—extracellular or secondary dehydration.

(B) A *possible* disturbance of acid-base equilibrium if loss of sodium and chlorine ions is not proportionate (see Fig 8).

Both changes produce clinical effects, but of the two I would submit that the former is the more important. In severe vomiting and severe diarrhoea the main serious effects are the same in both conditions and are due to secondary dehydration. The manifestations due to alkalosis

and acidosis respectively are of secondary importance. It has been unfortunate that it has so happened that historical progress of medical discovery caused attention first to become focused on acid-base disturbances. This accident of history has resulted in undue preoccupation with acid-base changes, in cases of the type described, to the relative exclusion of the more serious effects due to loss of extracellular osmotic pressure. In any event, if sodium chloride is administered, along with enough water, the kidneys will automatically restore the acid-base balance by appropriate differential excretion of sodium and chlorine ions. These remarks are not, of course, intended to apply to disturbances of acid-base equilibrium arising from causes other than asymmetrical loss of sodium and chlorine ions in alimentary secretions—that is, not to acid-base alterations from the excessive administration of acid or alkaline salts, overbreathing, or the accumulation of ketone bodies.

A Effects due to Loss of Osmotic Pressure

Lassitude, Apathy, Stupor—Anyone who has lived in the Tropics knows the feeling of extreme lassitude in hot weather and that it is alleviated by ingestion of extra salt. Caplan (1942) found fatigue and asthenia in 243 of 244 cases of heat exhaustion. McCance (1936) states: "We have all suffered from excessive fatigue and a general sense of exhaustion—Whitteridge and Niven both got into an extraordinarily interesting state, in which they were content to sit and do nothing in a chair for hours on end." Lassitude and apathy, progressing to stupor, were main features in the cases of heat exhaustion which I observed. In the hot seasons I was often struck by the apathy of men in hospital for sickness of various kinds, especially those eating poorly, examination of their urine for chloride generally demonstrated its absence. Black (1946) has recently published a paper showing how an increased sense of well-being and a return of vigour were induced in cases of chronic sprue in India by the administration of extra salt. Such men were not only losing salt by the skin, but also in their copious evacuations. Lassitude is an essential and more pronounced feature in pure salt depletion than in simple water deprivation.

Weakness—Muscular feebleness, as distinct from mere disinclination for effort arising from the lassitude, is definite. McCance (1936) describes how he found his jaw getting tired when shaving and noticed his jaws bring water to his mouth while eating. The myasthenia of Addison's disease is well known.

Headache—This is often present. It has the character of a low-pressure headache, it is much less noticeable than the subject gets out of the vertical position and lies down.

Giddiness and Tendency to Orthostatic Fainting—This is frequent. I saw it in many cases of heat exhaustion. Caplan (1942) noted it in 215 of 244 cases. Ladell et al. (1944) say: "The effect of standing was dramatic. The pulse became progressively more difficult to feel and rapid. The blood pressure fell and often could not be taken because the sounds were inaudible. The face became increasingly pale, began to sweat profusely, to complain of dizziness. He was obviously on the verge of syncope."

Normal Urine Volume (till Late Stages)—If the subject is drinking freely, urine volume is normal, or may be increased until the late stages, when nausea and vomiting occur, there is, however, a very slow excretion of water. A particular quantity of water ingested. McCance (1936) states: "We have all noticed that our water metabolism was not normal. After drinking a large amount of water, no diuresis would develop at the expected time, but hours later—possibly during the night—the diuresis

sign In Addison's disease delayed diuresis has been noted (Rowntree and Snell, 1931). It is the basis of the water-elimination test described by Robinson *et al* (1941). The delayed diuresis is usually ascribed to delayed excretion. I shall presently advance another hypothesis, which I have not seen elsewhere put forward—namely, that the delay may be chiefly or in part in *absorption* and that the water may remain overlong in the stomach and alimentary tract. Chloride is absent from the urine except in Addison's disease.

Absence of Thirst—This is most important. It has been laid down as an essential condition in the causation of pure salt depletion that there must be liberal intake, oral or parenteral, of unsalted water. However, even if intake is relatively low but not low enough to make the case one of predominant water depletion, there is no thirst, indeed, water is often repellent. I have seen men suffering from severe secondary dehydration refuse water or spit it out.

Anorexia—Nausea—Vomiting—These symptoms, in the progression indicated, are present in most moderate or severe cases. Associated with the anorexia is loss or perversion of taste. Caplan (1942) observed nausea in 152, and vomiting in 136, of 244 cases. He regarded 194 of these cases as mild and 50 as moderate or severe, vomiting as invariable in the latter group. Ladell *et al* (1944) noted vomiting in 73% of 45 cases. My own experience embraces a large number of cases, but unfortunately is impressionistic and unsupported by factual data, as the conditions of my hours precluded spending time on recording and I did not then consider publishing my findings. Indeed, the significance of some of the observations made did not become apparent until there was subsequent time for reflection. Anorexia, nausea, and vomiting are particularly important,

because they inaugurate a vicious circle which causes rapid deterioration (Fig 9). This train of events is well known in Addison's disease.

Weight Loss—This is marked, especially in the early stages, in spite of free water intake. It is consequent upon the secondary dehydration. The weight tends to be of the approximate order of 1 lb per 3.4 g of sodium deficit (McCance, 1936).

Changes in Appearance—Sufferers show signs of subcutaneous desiccation. The eyes are sunken from loss of orbital tissue fluid. In the late stages the appearance resembles the Hippocratic facies. The skin loses its elasticity so that pinched up folds do not smooth out on release. The patient no longer fills his skin and in extreme cases the skin of the fingers may be wrinkled (washerwoman's hands of cholera).

Cramps—Heat cramps have long been well known, especially by horse riders and firemen realized that they tend to be precipitated by water ingestion and prevented by salt intake. Caplan (1942) noted cramps in 142 (24 cases). Ladell *et al* (1944) in 70% of 45 cases.

Confusion and Delirium—I saw several men who had mental changes during and shortly after heat stroke. Some were just confused and disoriented—a state which can be seen in severe vomiting or diarrhoea. One young soldier was possessed by the delirium, he was for execution on the morrow, a sentence which was later to be made. Saphir (1935) has described an acute depletion of a sustained mild case as a multiple psychoneurosis.

Blood Changes

Plasma Sodium and Chlorine—When salt depletion is severe there is a fall in the plasma concentration of sodium and chlorine. Most published figures relate to plasma chloride, expressed as sodium chloride, which may fall in extreme cases from the normal levels of 560 to 630 mg per 100 ml to 300 mg per 100 ml or even slightly lower. As the sodium ion is the more important from the osmotic standpoint, data regarding falls in sodium levels would be more relevant.

Blood Urea—The blood urea rises (McCance and Widdowson, 1938). Ladell *et al* (1944) found it raised in all cases of salt-depletion heat exhaustion, 12 out of 26 cases had levels above 100 mg. In spite of high blood urea and low urine volumes in their cases, the urea concentration in urine was low. In 9 cases the ratio between concentrations of urea in urine and plasma was measured and found to average 40:1. In severe vomiting and diarrhoea figures of the order of 100 to 200 mg per 100 ml or higher are commonplace. In experimental adrenalectomy (Harrop *et al*, 1933) or in Addison crises the blood urea may be similarly raised.

Plasma Volume—There is shrinkage of the plasma volume leading to haemoconcentration. Leonard Rogers (1908, 1909a and b, 1911, 1915, 1916, 1921) demonstrated many years ago how in severe cholera cases as much as two-thirds of the plasma volume may be lost. A similar loss may occur as a result of vomiting. In salt depletion due to sweating McCance (1938) produced in volunteers extracellular-fluid reductions of 28 to 38%, Ladell *et al* (1944) found plasma-volume reductions up to 50% in heat exhaustion. In extreme salt depletion from vomiting, gastric or intestinal suction, fistulae, diarrhoea, sweating, or Addison's disease, a loss of as much as one-half to two-thirds of the plasma volume is possible. It is probable that definite circulatory manifestations (see below) hardly become evident until the plasma volume has been reduced by 15%. A systolic blood pressure below 90 mm Hg probably indicates at least a 25% reduction. The relative normal ratio of plasma volume to tissue-fluid volume is about 1:4, but when the extracellular fluid is reduced through salt depletion the reduction of the tissue-fluid portion is relatively greater than that of the plasma portion (see Fig 4b) because of increasing colloid osmotic pressure as the plasma protein molecules become concentrated. A reasonable rough assumption is that loss of a litre of plasma volume (normal plasma volume being approximately 3 litres) means a total loss of extracellular fluid of the order of 6 to 7 litres.

Plasma volume may be measured directly, and Evans (1945) in a valuable paper discussing the significance of alterations in blood volume, has rightly stated that blood-volume determinations should be part of the laboratory routine procedure of all hospitals, or, in a non-anaemic subject the plasma-volume reduction may be deduced from data relating to haemoconcentration. Leonard Rogers was a pioneer in this field. Relevant data are the haemoglobin percentage, the haematocrit reading, and the plasma and whole-blood specific gravities. The last-named, as Rogers realized is perhaps the most convenient for quick practical use. It may be determined by the falling-drop technique in graduated mixtures of glycerin and water (Rogers) or in graduated copper sulphate dilutions as proposed by Phillips and van Slyke (1943). The correlation between blood gravity and haemoglobin and haematocrit percentages is shown with clarity in their line chart. If the haemoglobin percentage is determined directly, or indirectly, the plasma volume can be

FIG 9—Vicious circle of events in salt depletion

adaptation of a form of calculation proposed by Black (1940b)

$$\text{Plasma loss (in litres)} = 5 - \frac{5 \times \text{Hb}_1}{\text{Hb}_2}$$

where $\text{Hb}_1 = 100\%$, $\text{Hb}_2 =$ value in patient, and 5 litres is the assumed normal blood volume. I would say that, as a very rough rule, in secondary dehydration the plasma loss may be multiplied by 6 to give the total extracellular fluid loss. In extreme salt depletion, with a loss of one-half to two-thirds of the plasma volume, the consequent haemoconcentration may produce such high blood values as the following: specific gravity, 1064 to 1070, haemoglobin, 20 to 23 g per 100 ml, haematocrit, 58 to 64%, red cell count, 7 to 8 millions per c mm. Such findings indicate an extracellular fluid loss in the region of 7 to 10 litres for a 70 kg man, or about 2 imperial gallons.

Blood Viscosity—Haemoconcentration increases the viscosity of the blood (Whittaker and Winton, 1933, Holbrook and Watson, 1939, Evans, 1942). Kekwick and I (1940) studied the flow of blood through capillary tubes in devising a capillary regulator, instead of a screw-clip, for obtaining a more constant flow in drip blood transfusions. We then realized the tremendous part that viscosity must play in determining the flow through small blood vessels and capillaries. Poiseuille's equation is said to hold for such flow (Whittaker and Winton, 1933, Seligman *et al*, 1946)

$$\text{Flow} = \frac{\text{Pressure}}{\text{Viscosity} \times \text{Resistance}} \times \text{Constant}$$

Hence, if the viscosity should be doubled the flow will be halved. Wynne Willson and I (1940) did some work with various concentrations of red cells in citrated or heparinized plasma in an endeavour to ascertain the correlation between progressive haemoconcentration and increase of viscosity. Our experiments were of a rough-and-ready character, designed to produce a quick answer to urgent resuscitation problems, and were not brought to a stage fit for publication. However, they showed that when the red cell count is around $7\frac{1}{2}$ millions per c mm the blood viscosity is about double what it is when the count is 5 millions per c mm.

The Circulation

If the decrease in plasma volume is at all severe the patient passes into a state of oligæmic circulatory failure or "shock". This is well understood in relation to severe vomiting and diarrhoea, and I have seen it often in heat exhaustion. Caplan (1942), reporting on 50 moderate and severe cases, states "The patients exhibited all the signs of shock. The skin was cold and clammy—the blood pressure in the severe cases was indeterminable and in the moderate cases the systolic pressure was always below 95 mm Hg—commonly 60 to 90—and the pulse pressure 2 to 10 mm Hg." The peripheral failure of adrenalectomized animals or of patients with Addison's disease in crises is well known. The main factors in the production of circulatory failure are (a) the reduction in blood volume, and (b) the increased blood viscosity. The effect of blood-volume reduction in producing shock (Robertson and Bock, 1919, Keith, 1919) has been much studied in the recent war (Kekwick, Marriott, Maycock, and Whitby, 1941, Dick, 1944, Evans, 1945). Less attention has been devoted to the effect of increased viscosity, which, of course, also occurs in plasma loss in burns and injuries due to crushing. I suggest that in the circulatory failure of severe salt depletion it plays an important part. Seligman Frank, and Fine have recently published (1946) an experimental study on the haemodynamic effects of raised blood viscosity, and have shown its importance.

The clinical picture of the circulatory failure of salt depletion is the familiar one of increasing oligæmic

vasoconstrictive shock. The patient is pallid and often in a clammy sweat. The extremities are cold (if atmospheric conditions allow cooling). The blood pressure is at first maintained and the diastolic pressure may be raised (Ladell, Waterlow, and Hudson, 1944) but later falls, and the pulse pressure is diminished. The veins are empty. The pulse deteriorates, first in force and then in tension, and usually quickens. Cyanosis of lips and nails appears as the condition develops. When the systolic blood pressure drops to about 70–80 mm Hg anuria occurs. The mental condition is not as alert and clear as in haemorrhagic shock. The patient tends to pass into a confused stuporous condition and finally into coma. An important point to note in patients with oligæmic failure is the danger of sudden death from changes of position (Evans *et al*, 1944), such as sitting the patient up to examine the chest.

Water Absorption

I have mentioned above how the subjects of pure salt depletion are not thirsty, and how they develop anorexia, nausea, and vomiting. In patients with severe heat exhaustion to whom I endeavoured to give saline by mouth I noted that often the saline, if not vomited, would stay in the stomach, which could be seen, through the abdominal wall, to be greatly distended. There seemed to be definite pylorospasm coupled with atony of the stomach. Other observations led me to believe that a tendency to spasm of the sphincters and lack of tone of the gut prevailed throughout the alimentary canal. I consider that the delayed diuresis of salt depletion may be largely a question of delayed absorption. It is my impression that fluids remain much longer than usual in the stomach, and that even when the pylorus is passed absorption is slow. I have recently had under my care a case which was typical of many others I saw before the war without appreciating their significance.

A woman aged 58 with pyloric stenosis due to old duodenal ulceration, and with the usual history of vomiting large amounts had been vomiting intermittently for 10 years and daily for about a month. On admission she was stuporous and appeared to be dehydrated, and there was loss of skin elasticity. Her blood pressure was 90/50 mm Hg, the plasma chloride, as NaCl, was 286 mg, and the blood urea 190 mg per 100 ml. During the first three days of treatment she received intravenously 23 pints of isotonic saline solution (= 13 litres containing 110 g of NaCl) and 8 pints (4.5 litres) of isotonic glucose solution. She also was given 3 pints (1.7 litres) of water by mouth. Owing to incontinence, urine measurement was not possible during the first two days. Her output of urine on the third day was 33 oz (937.6 ml) containing 3 g of NaCl. By the fourth day she appeared almost recovered and the plasma NaCl had risen to 524 mg per 100 ml. Intravenous fluid administration was stopped and on this and the next four days she received by mouth 19 pints (11 litres) of fluid plus some solid food. There was no abdominal distension; therefore this volume had successfully passed her previously impassable pylorus. Pyloric stenosis was subsequently confirmed by barium meal and at operation.

Sanchez-Vegas and Collins (1946) have reported upon 50 patients with pyloric obstruction due to duodenal ulcer. Gastric retention disappeared in all except 3 under treatment, averaging five days, in which the chief measure seems to have been administration of large amounts of sodium chloride in hypertonic solution. The main purpose of the communication of these authors was not to make the point, which I am tentatively

FIG 10—The vicious circle suggested in cases of salt depletion with pyloric obstruction

suggesting, that pylorospasm may be a consequence of salt depletion, but to urge that urine chloride estimations are a better guide to progress than plasma estimations

My observations on cases of heat exhaustion suggest that patients with pyloric obstruction may enter a vicious circle (Fig 10). There is scope for radiological investigation of gastro-intestinal function, especially the emptying time of the stomach, in salt-depleted volunteers. It seems that salt depletion may also explain many cases of "paralytic ileus" in which there is no peritonitis. The effect of saline on peristalsis has been demonstrated by Eitel and Loeser (1934) and by Perazzo (1937).

B Effects due to Disturbance of Acid-Base Equilibrium

When there is considerable asymmetrical loss of sodium or chlorine ions—such as the predominant loss of sodium in diarrhoea or the predominant loss of chlorine in vomiting (Fig 8)—there is a disturbance of acid-base equilibrium, with a relative increase of bicarbonate with respect to chlorine in vomiting and a relative recession of bicarbonate in diarrhoea. The carbon-dioxide-combining power (alkali reserve plasma bicarbonate) in ml of CO_2 per 100 ml of plasma may be over 100 after vomiting or under 20 after diarrhoea. As Gamble (1937) has said the bicarbonate ion plays a 'mendicant' part—it takes what base it can get.

Much attention has been directed in the past to these tendencies to alkalosis and acidosis, and many of the symptoms which have just been described, and attributed to loss of electrolyte osmotic pressure, were stated to be due to the distortion of acid-base balance. However, this is surely untrue, because all the manifestations, here called osmotic, may be seen in cases of severe sweating where there is no gross acid-base change, also all the manifestations are common to cases of either severe vomiting or severe diarrhoea. Indeed, apart from the different direction of ejection of alimentary secretions, there is little difference in the clinical picture presented by sufferers from emesis or catharsis. It is true that alkalosis or acidosis may have some intensifying effect on the anorexia, nausea, and vomiting which are certainly prominent enough in simple symmetrical sodium and chlorine depletion (sweating). Alkalosis may increase cramps through its tendency to cause tetany, but cramps are quite a marked feature of choleraic diarrhoea in which there is acidosis, and are a characteristic feature of the salt depletion due to sweating. The only effect which seems mainly or wholly attributable to alkalosis or acidosis, when caused by vomiting or diarrhoea, is perhaps some difference, of little practical significance, in the character of the breathing.

The mechanism of death in pure salt depletion seems quite clearly to be circulatory failure due to a combination of reduction of blood volume and increase of blood viscosity.

Quantitative Correlation of Clinical and Pathological Manifestations with Amount of Salt Deficit

The ability to estimate the degree of deficit from the overall picture presented by the patient is a matter of great practical importance. It is so because, so far as I am aware, there is no other reliable index. The concentration of plasma chloride, expressed as NaCl, is often used as an index, but a little reflection will show, as Abbott (1946) has pointed out, that the concentration of chlorine or sodium cannot mirror the total loss of these ions because adjustment mechanisms, especially renal, work to preserve, so far as is possible normality of concentration in the effort to sustain the prime essential—isotonicity. When plasma

sodium and chlorine tend to fall the kidneys excrete water and as already explained, there is sacrifice of plasma volume in order to preserve electrolyte concentration. How, then, can any measure of this concentration determine total deficit? Significant falls in plasma chlorine or sodium values only occur when total deficits are very gross. This point is well brought out by Sanchez-Vegas and Collins (1946) in their study of 50 cases of pyloric obstruction. All these patients had either very little chloride in their urines or none at all and all required large amounts of sodium chloride to restore renal excretion of chloride to normal. Yet only 10 out of the 50 had plasma chloride concentrations expressed as NaCl lower than 510 mg per 100 ml, although 29 had blood urea concentrations exceeding normal limits.

From the basis of personal experience I would suggest that cases of salt depletion may be divided into three grades.

(1) *Slight to Moderate Depletion*—Low concentration or absence of chloride in the urine (except in Addison's disease) with lassitude and maybe giddiness and orthostatic fainting indicates a deficit of up to 0.5 g per kilo of body weight. In a 70 kg man this represents a deficit of up to 4 litres or 7 pints of isotonic saline.

(2) *Moderate to Severe Depletion*—Absence of chloride in the urine (except in Addison's disease) with lassitude, giddiness and fainting with anorexia and maybe nausea and vomiting, and with a fall of blood pressure but with a systolic pressure above 90 mm Hg, points to an approximate deficit of 0.5 to 0.75 g per kilo which in a 70 kg man would represent a deficit of 4 to 6 litres (7 to 11 pints) of isotonic saline.

(3) *Severe to Very Severe Depletion*—Absence of chloride in the urine (except in Addison's disease) with apathy, stupor, vomiting and a systolic blood pressure of less than 90 mm Hg suggests an approximate deficit of 0.75 to 1.25 g per kilo—that is a deficit of 6 to 10 litres (11 to 18 pints) of isotonic saline in a 70 kg man.

The above divisions represent a very rough classification and are put forward merely as a crude guide to appraisal of salt deficit. There will be individual cases forming exceptions but at the same time, it is suggested that even rough clinical criteria may be better than seemingly accurate and scientific measurements of plasma concentrations of sodium and chlorine—not, of course that these should be omitted.

A Useful Test

It will be noticed that absence of chloride in the urine is accorded a place of first importance. For several years I have used the very simple quantitative test described by Fantus (1936). This can be done in a minute and is simpler than testing for albumin or sugar as no heating is needed. The requirements for performing the test are a small test-tube, a small pipette ('fountain-pen filler'), 20% potassium chromate solution, 2.9% silver nitrate solution, some distilled water for rinsing the pipette. It is essential that the same pipette shall be used throughout so that the size of the drops shall be the same.

Technique—Ten drops of urine are measured into the test-tube. The pipette is rinsed and one drop of potassium chromate solution—the indicator—is added. The pipette is rinsed again and then the silver nitrate solution is added a drop at a time and the test tube shaken after the addition of each drop. The end point is a sharp colour change from yellow to brown. The number of drops needed to produce the end point gives the concentration of chloride in the urine expressed in grammes of NaCl per litre—for example 5 drops = 5 g of NaCl per litre. It is important to make a preliminary test with distilled water to make sure that there is no contamination of the chromate with chloride.

This very simple test is most useful not only in diagnosis but also in the control of treatment.

diagnosis chloride should be regarded as "absent" if the end-point colour change occurs with the first drop. This may happen in normal persons if the urine is very dilute because a large amount of fluid has been taken, but if it occurs in the absence of diuresis it is indicative of salt depletion, though the depletion may not have reached a degree sufficient to cause symptoms. In concentrated urine (with a specific gravity of more than 1020) less than 3 g per litre suggests depletion. If the urine contains 5 g per litre or more the patient, except in Addison's disease or during the administration of intravenous saline, is unlikely to be suffering from salt depletion. The test was found useful in India and South-East Asia Commands during the war in the detection of salt-depletion heat exhaustion and of salt depletion complicating many medical and surgical illnesses. In M I room work it was valuable in the hot weather as a quick method of separating cases of salt-depletion heat exhaustion from those of neurotic collapse and ill-health from other causes. White (1943) so applied it at Air Headquarters, Delhi, during June and July, 1943, to a series of 140 patients, of whom 29 were proved to be suffering from heat exhaustion. Its potential scope is not as great in temperate as in hot climates but is still enormous, for it is applicable in the diagnostic assessment and therapeutic regulation of all cases of threatened or actual dehydration or of overt oedema. Whenever fluid tends to be lost from or retained in the body, the measurement of urinary excretion of sodium chloride is as important, in many instances more important, than the measurement of urine volume. It is my belief that the means for performing this simple test should be available in all ward test-rooms and in every doctor's bag. A similar simple quantitative test for sodium would be even more valuable if it could be evolved.

(To be concluded with a full list of references in our next issue)

MEDICAL ASPECTS OF PENICILLIN TREATMENT

BY

B. A. YOUNG, MD

Medical Superintendent St Alfege's Hospital Greenwich

This paper is based on a survey of the cases treated in the medical wards of St Alfege's Hospital with systemic penicillin alone, or with systemic and local penicillin combined, from January, 1945, to September, 1946. In all, 129 patients were so treated. The cases are unselected, except that they were considered worthy of penicillin therapy on clinical or bacteriological grounds, and are consecutive cases. They were not the subject of special investigation as part of an experimental trial of penicillin treatment, but we have been continually alive to the fact that each case undergoing penicillin treatment is, even at the present time, an experiment in a new form of therapy, the application of which is by no means finally settled.

Our first regular supplies of penicillin became available in April, 1945, when we were allocated 5,000,000 units a month. This quota was gradually increased until at the time of writing our monthly consumption is between 150,000,000 and 200,000,000 units. The majority of cases were therefore treated in 1946. The 129 cases include the most serious and potentially fatal illnesses treated. An analysis according to the final diagnosis is shown in Table I.

The pneumonias form the largest group with 53 cases. Carbuncles, meningitis, and empyema are the next largest with 13, 11, and 10 cases respectively. The appearance of

carbuncles, cervical adenitis, and diabetic gangrene among a series of cases treated in medical wards alone is part of the revolution in medical practice which penicillin has

TABLE I—Medical Cases Treated with Systemic and Local Penicillin

Disease	No of Cases	Disease	No of Cases
Respiratory diseases		Streptococcal tonsillitis	4
Pneumonia	53	Diabetic gangrene	3
Acute bronchitis	3	Perinephric abscess	2
Empyema	10	Cellulitis	1
Lung abscess	2	<i>Staphylococcus aureus</i>	1
Carbuncles	13	Septicaemia	1
Meningitis	11	Vincent's angina	1
Secondarily infected skin lesions	8	Acute pyelonephritis	1
Acute nephritis	6	<i>E. coli</i> septicaemia	1
Subacute bacterial endocarditis	5	Lobar pneumonia	1
Cervical adenitis	5	Pemphigus chronic nephritis	1

brought about. Particularly, and most dramatically, in the case of carbuncles is this change of practice welcome, most of all to the patient.

Below is given an analysis of the results of treatment of the more important groups of diseases, with a brief description of the methods used, and such points of importance bearing on treatment that have been brought to light.

Pneumonia

From January to December, 1945, 12 cases of pneumonia were treated, with 5 deaths, and from January to September, 1946, 41 cases, with 3 deaths. This represents an overall mortality of 15%. Of the 53 patients 26 were over 40 years of age and 10 were under 6 months, and the majority were cases of great severity. During the first period penicillin was scarce and dosages were in consequence low. The figures for the second period, giving a mortality of 7.3%, must be regarded as very gratifying. Four of the eight fatal cases were moribund on admission and death occurred within 24 hours, three had signs of congestive cardiac failure on admission, and one was a premature infant. Seven patients who recovered, two who improved, and five who died were also treated concurrently with sulphonamides. Fifteen cases received penicillin after the infection had failed to respond to sulphonamide therapy.

TABLE II—Cases of Pneumonia

Variety	Recovery	Improvement	No Change	Death	Total
Lobar unclassified	11	3	—	3	17
Bronchopneumonia unclassified	11	—	2	5	18
Pneumococcal	4	—	—	—	4
Staphylococcal	4	1	—	—	5
Streptococcal	4	—	—	—	4
Mixed flora	4	—	—	—	4
Atypical	—	—	1	—	1
Total	38	4	3	8	53

The bacteriological classification of the cases is not complete, partly because many of the patients treated were too ill or too young to produce sputum, and partly because we were loath to ask too much of our ever-willing but overworked laboratory staff. We now regard a bacteriological diagnosis, with a penicillin-sensitivity test of the organism, as an essential in the penicillin treatment of pneumonia. Such information offers valuable guidance to the physician particularly on the necessity for increasing the dose or for prolonging the course, in a case not initially responding to penicillin. Without this information he works in the dark. It may be significant that of the cases bacteriologically classified none were fatal.

Indications for Penicillin Treatment in Pneumonia—Administration of sulphonamides is still our method of choice. Our indications for penicillin are (1) Cases with a bad prognosis owing to clinical severity with signs of extreme toxæmia, old age, and infancy, particularly prematurity. In these cases penicillin and the sulphonamides

may be combined (2) Cases failing to respond to sulphonamides within 36 hours, or cases known to be sulphonamide-sensitive (3) Cases with congestive heart failure or renal disease where the excretion of sulphonamides is likely to be deficient (4) Cases with complications such as diabetic ketosis or anaemia

Treatment

Up to April, 1946, the usual adult dose of penicillin was 30,000 units initially by intramuscular injection, followed by 15,000 units three-hourly (120,000 units in 24 hours) For the past six months the initial dose has been 60,000 units, followed by 30,000 units four-hourly (180,000 units in 24 hours) In cases with a very bad prognosis the dose has been increased to 60,000 units four-hourly (360,000 units in 24 hours) The dose in infants has been of the order of 2,000 to 4,000 units per pound (454 g) of body weight in the 24 hours, depending on the severity of the infection Doses for children have been intermediate between this and the adult dose All doses are made up to a volume of 1 ml with distilled water Larger volumes are likely to increase the discomfort of the injection

Increased supplies of penicillin have therefore permitted the administration of larger doses at longer intervals, to the benefit both of patients and of nursing staff The duration of treatment has been from 5 to 10 days, the majority of cases receiving a six-day course Cases have responded to treatment in from one to four days—in most instances within 48 hours Increased dosage at greater intervals is now a growing tendency in our practice We are experimenting with doses of 250,000 units at intervals of 8 to 12 hours The number of cases so treated is small, but the impression gained up to the present is that 250,000 units eight-hourly gives a more satisfactory response than a similar dose 12-hourly 500,000 units 12-hourly is also under trial This winter we should treat enough cases of pneumonia to form a definite opinion on this system of dosage

I have included the above generalizations under the pneumonias as they form by far the largest group These remarks apply equally to the treatment of my other groups

Empyema

Ten cases of empyema have been treated, with eight recoveries and two deaths (Table III) Of the two deaths, one was that of a woman of 80 who died within 24 hours of admission, the other case was complicated by the presence of chronic pulmonary tuberculosis and grew *Haemophilus influenzae* in the pleural fluid

TABLE III—Cases of Empyema

Variety	Recovery	Death	Total
Pneumococcal	3*	1†	4
Staphylococcal	1*	—	1
Streptococcal	3	—	3
No organism	1	—	1
Influenzal (chronic pulmonary tuberculosis)	—	1	1
Total	8	2	10

* One pneumococcal and one staphylococcal case were treated by surgery
† Female patient aged 80, moribund, death within 24 hours

Treatment has been by the administration of systemic penicillin in doses of 30,000 to 60,000 units four-hourly, with repeated aspiration of the fluid and intrapleural injection of 60,000 to 120,000 units of penicillin in 20 to 50 ml of distilled water on alternate days The pleural fluid, given a penicillin-sensitive organism, is usually sterile after the second intrapleural injection, five to seven injections being the usual number Aspiration must be complete and be continued for a prolonged period if a satisfactory result is to be obtained In the majority of our cases we were

fortunate in beginning penicillin treatment early in the disease In two cases surgery has been necessary, rib-resection being carried out The indications for surgery are a thick exudate which cannot be aspirated, empyemas coming under treatment late in the disease, loculation of the fluid, and failure to sterilize the empyema with penicillin

The series is too small for a dogmatic opinion to be given, but my impression is that if aspiration and penicillin replacement are started early, with a penicillin-sensitive organism, good results can be obtained by aspiration and penicillin injection only provided aspiration is frequent, continued, and complete If surgery is indicated the patient is handed over to the surgeon in good condition, without toxæmia and with a sterile effusion

Meningitis

Eleven cases have been treated, with seven recoveries and four deaths (Table IV) Of the four fatal cases, one was an influenzal meningitis, one proved at necropsy to be a case of meningococcal meningo encephalitis (in this case, although the cerebrospinal fluid became sterile two days after treatment with intrathecal and systemic penicillin, no clinical improvement resulted), the third was low-grade meningitis, with otitic hydrocephalus which did not respond to penicillin treatment the patient dying after operation at a cranial surgery unit The fourth, a meningitis of unknown aetiology proved fatal within 24 hours of admission

TABLE IV—Cases of Meningitis

Variety	Recovery	Death	Total
Meningitis meningococcal	2*	—	2
Meningo-encephalitis (meningococcal)	—	1*	1
Meningitis pneumococcal	2*	—	2
Influenzal	2*	1*	3
acute purulent	1*	1*†	2
low grade with otitic hydrocephalus	—	1*	1
Total	7	4	11

* Also treated with sulphonamides

† Systemic penicillin only

‡ Death within 24 hours of admission

In view of the excellent results obtained with sulphonamides, intrathecal penicillin is probably unnecessary in cases of meningococcal meningitis The fever hospitals can advise us with more authority on this point Our cases were treated with sulphadiazine and systemic penicillin only, and made rapid recovery

Pneumococcal meningitis was treated by the intrathecal injection of 10,000 to 30,000 units of penicillin on alternate days for three injections In each case the fluid was sterile after the first injection and recovery dramatic Intrathecal therapy was supplemented by 60,000 units of penicillin four-hourly by intramuscular injections for 10 days and full doses of sulphadiazine

The three cases of meningitis due to *H. influenzae* are most interesting and instructive Dr B Gottlieb, in whose wards they were treated, is shortly submitting for publication a detailed account of their investigation and treatment The *H. influenzae* was thought to be penicillin-resistant We now realize that this organism is only relatively resistant to penicillin Penicillin-sensitivity tests in one case showed that the organism (*H. influenzae*, Pittman type b) although insensitive to a penicillin solution of 10 units per ml, using the punch-plate technique, was inhibited by the same technique using a solution of 100 units per ml The same organism was not sensitive to sulphadiazine or sulphathiazole in concentrations of 10 mg per ml

The first case, that of a child of 10 months was treated with 27 intrathecal injections of 30,000 units of penicillin with 15,000 units three hourly systemically to a total of 4,440,000 units and full doses of sulphadiazine After the

intrathecal injection the cerebrospinal fluid became sterile but in spite of continued treatment the organism reappeared and the child died after nearly three months' treatment.

The second patient, a child of 21 months, received 10 intrathecal injections of 50,000 units in 15 days, 120,000 units three-hourly systemically for 48 days (46,000,000 units), and full doses of sulphadiazine. The cerebrospinal fluid became sterile after six intrathecal injections, and the child made a full recovery.

The third and most recent case, that of a child of 10 months, received three intrathecal injections of 50,000 units and three of 30,000 units in 10 days, with 60,000 units four-hourly systemically for 16 days (5,760,000 units). The fluid was sterile after the third day and the child made a rapid and full recovery. The dosage has been progressively increased from the first to the third case, with an improvement in the result.

These three cases are of the greatest importance in demonstrating that resistance may be purely relative, and the administration of overwhelming doses of penicillin will save life where smaller doses will fail. Close co-operation with the bacteriologist is essential in the treatment of such cases.

To minimize the risk of meningeal reactions, only pure penicillin of a concentration of 1,660 units per mg is used for intrathecal injection, and to lessen the even greater risk of introducing infection by a penicillin-resistant organism each dose is made up separately in a sealed ampoule. One reaction in the form of convulsions was noted in the 10-months-old infant, three convulsions occurring immediately after the sixth and last intrathecal injection. The child appeared very shocked during the reaction, but made a rapid recovery.

A problem which the physician often faces in treating meningitis is to decide on the line of action to be taken if a turbid cerebrospinal fluid is withdrawn and no immediate expert bacteriological opinion is available. The introduction of penicillin into the cerebrospinal fluid is not without risk, and it appears to be unnecessary in meningococcal meningitis. The risks are very slight, however, if the precautions I have previously mentioned are taken. My practice is to wait for a bacteriological diagnosis, if one can be obtained within a few hours, before giving intrathecal penicillin. If this is not available 10,000 units of penicillin are given intrathecally pending a bacteriological diagnosis on fluid previously removed. In very ill patients penicillin is given intrathecally immediately turbid fluid is withdrawn.

Carbuncles

Thirteen cases of carbuncle have been treated. Nine uncomplicated cases responded rapidly to 30,000 units given four-hourly. A disappearance of malaise and toxic symptoms occurred after 24 hours, and there were signs of local improvement on the second or third day. Treatment was continued for from five days in the smaller carbuncles to seven to nine days with large carbuncles. More recently, excellent results have been obtained by the administration of 100,000 units twice daily to a number of patients not admitted to hospital. Four cases had complications—two with staphylococcal septicaemia and bronchopneumonia and two with diabetes mellitus. The former were gravely ill, but made remarkable and rapid recovery with moderate doses of 15,000 units three-hourly for 14 days. These patients were treated early in 1945, the larger doses available later would have resulted in a more rapid response. One of the diabetics, treated with 40,000 units four-hourly for 7 days, relapsed with a slight flaring-up of the local infection. She quickly responded to a second course. The second case required 30,000 units four-hourly for 12 days. It would seem wise to continue the penicillin course in a diabetic for a longer period than in an uncomplicated case.

Before summarizing the more important general points I should mention that we were not able to convince ourselves that systemic penicillin influenced the course of the six cases of acute haemorrhagic nephritis so treated.

Summary and Conclusions

The following are the more important points that have arisen in our experience during the treatment of cases with systemic or systemic and local penicillin.

- 1 A bacteriological diagnosis should be obtained whenever possible and penicillin sensitivity tests on the organism carried out. This should not delay the institution of treatment in urgent cases, which may be started while bacteriological investigations are in progress.

- 2 Intermittent intramuscular therapy is our method of choice, injections being given four hourly. The usual dose in adults is 30,000 units four hourly, with 60,000 units four-hourly in severe infections. The present tendency is further to prolong the intervals with increase in dosage. More work on these lines is necessary.

- 3 The volume of a single dose should not exceed 1 ml. Up to 250,000 units of the penicillin at present supplied (1,400 to 1,500 units per mg) can be dissolved in this amount of distilled water.

- 4 Intrathecal therapy should be undertaken with the strictest aseptic technique, only pure penicillin of 1,660 units per mg should be used. Each dose should be made up separately in a sealed glass ampoule.

- 5 The scope of penicillin treatment should include that group of organisms previously classified as penicillin resistant. Tests for penicillin sensitivity should be carried out in concentrations up to several hundreds of units of penicillin per ml before resistance is considered a contraindication to treatment. This conclusion I consider to be of the greatest importance.

Penicillin therapy calls for the highest standard of diagnostic technique from the physician, and for an experimental and scientific approach to each case under treatment. A constant survey of the results obtained with given dosages for the various diseases is necessary until the position regarding optimum dosage and method of administration is stabilized. This may not be for some years.

The demands on the pathologist are increasing and will continue to increase with penicillin and allied therapy. His laboratory must be adequately staffed to meet these demands. The pharmacist is an indispensable member of the "penicillin team" and must be able to deal adequately with all forms of penicillin preparations, including those in non-hospital practice calling for a licence under the Therapeutic Substances Act. His pharmacy must be equipped at least up to the standard demanded by the Act.

More Recent Experience

Since November, 1946, when this paper was written, twenty adults suffering from pneumonia have been treated by the systemic administration of 250,000 units of penicillin at twelve-hourly or eight-hourly intervals. These cases were not selected, as were those of the paper, on grounds of clinical severity but were consecutive patients suffering from pneumonia admitted to two medical wards. Of the twenty cases, sixteen were classified as lobar pneumonia and four as bronchopneumonia. A radiological diagnosis was obtained in each case. Three cases were treated by 250,000 units twelve-hourly. One (pneumococcus) responded satisfactorily, two (*Streptococcus viridans*, penicillin-sensitive) gave responses delayed to four and seven days, as shown by the temperature, pulse, and clinical condition.

On the experience of the two latter cases the dosage was increased to 250,000 units eight-hourly for an average of six days. Of the seventeen cases so treated, thirteen were

classified as lobar pneumonia and four as bronchopneumonia. The predominating organisms were pneumococci and a mixed catarrhal flora. The patients' ages ranged from 16 to 87 years (two cases), with an average of 50 years. There were fifteen recoveries and two deaths. One of the two fatal cases, a man of 45, was admitted in a semi-conscious condition with severe toxæmia and congestive cardiac failure. He died within eighteen hours of admission after receiving two injections of 250,000 units of penicillin. The second fatal case, a man of 87, died on the seventh day of treatment from congestive cardiac failure, with auricular fibrillation and arteriosclerotic myocardial degeneration, after an initial apparent response to therapy. The fifteen patients who recovered all showed an excellent response to penicillin treatment. The temperature and pulse fell by crisis, and there was a great improvement in the clinical condition with loss of toxæmia in an average of thirty-six hours from the beginning of treatment. The average duration of stay in hospital of these patients was fourteen days.

My thanks are due to Dr B. Gottlieb, senior resident physician at St. Alfege's Hospital, for the invaluable help he has given me in preparing this paper, and to many other members of the medical staff who have assisted in the treatment of these patients. I am grateful to Dr E. N. Allott, of the Lewisham Group Laboratory, for his generous co-operation and advice which have meant so much to us in developing penicillin treatment. Finally I would thank Mr. White, the chief pharmacist, whose skill and ingenuity in dispensing this new and labile substance in all its forms have been a stimulating example of the high pharmaceutical technique we now expect from our pharmacists.

THE PLACE OF UNILATERAL RENAL DISEASE IN HYPERTENSION

BY

CHRISTOPHER HARDWICK, M.D., M.R.C.P.

Assistant Physician to Guy's Hospital, Wing Commander R.A.F.V.R.

AND

ALEC W. BADENOCH, M.D., Ch.M., F.R.C.S.

Surgeon to St. Peter's Hospital, Surgeon and Urologist to the Metropolitan Hospital, Wing Commander R.A.F.V.R.

Until recently hypertension has been the province of the physician and, apart from blood-letting, its treatment has been mainly rest and a restriction of activity. Now, however, there is a surgical approach to this very great problem, and attacks have been made along both direct and indirect lines. *Direct* In cases in which unilateral renal disease has been found it may be assumed that this plays some part in the genesis of the hypertension, and the offending organ may be excised in an endeavour to remove this cause. *Indirect* By interruption of the sympathetic nervous system a lowering of the blood pressure has been obtained. All operations of this type have their effect irrespective of the aetiology of the hypertension, and do not attempt to remove its cause.

This paper is concerned with the direct line of attack. It has been our routine to perform excretion pyelography in every case of severe or considerable hypertension which has come under investigation. If at this examination both kidneys do not show a normal contour of pelvis and calices, then further investigation by cystoscopy and retrograde pyelogram has been undertaken. The following cases of hypertension occurring in association with renal disease have been encountered, and it is desired to put them on record.

Case 1

A flight-lieutenant aged 38 noticed puffiness of the eyelids and swelling of the ankles in June 1943. This persisted and became gradually worse. In September, 1944, he had an attack of acute tonsillitis and at a medical board was found to have a raised blood pressure and albuminuria. For some years he had had frequency of micturition. He was admitted to an R.A.F. hospital on Jan. 12, 1945, and was seen to be a well-nourished man with no demonstrable oedema. The blood pressure was 215/140. The heart sounds were normal. Nothing abnormal was found in chest and abdomen. The blood urea was 33 mg per 100 ml. Van Slyke: first hour 85%, second hour 92%. There was no albumin or deposit in the urine. A radiograph showed a calculus in the pelvis of the left kidney. He was given 21 days' leave and returned to hospital on Feb. 13. A radiograph showed the calculus to be in the same position. Blood urea, 38 mg per 100 ml. Blood pressure 190/130.

On Feb. 18 the left kidney was exposed through a curved loin incision. It appeared normal in size and consistency, but was rather adherent to the perinephric fat. The pelvis was cleared and opened posteriorly, and the stone was removed. A bougie was passed down the ureter easily and the opening in the pelvis was sutured. The wound was closed and a rubber drain inserted. He passed some blood stained urine the following day, and there was a slight leakage from the drainage-tube for the first three days after operation. Convalescence was satisfactory. On March 14 the blood pressure was 180/120.

Case 2

A wireless operator aged 25 with 4½ years service began to have headaches about June 1944. These became more frequent, and about the beginning of May 1945 he noticed that the left side of his field of vision was blurred. His appetite was good, weight steady and bowels regular. There were no urinary symptoms. Past history revealed nothing relevant.

On May 30 he was admitted to an R.A.F. general hospital overseas. His right vision was 6/6, left vision 6/6. The fundus of the right eye showed a cotton wool like horseshoe shaped area enclosing the macula nasally and the disk was oedematous. There were one or two small haemorrhages and a patch of exudate in relation to the superior nasal vessel. The left fundus showed similar changes. The urine contained albumin +. The blood pressure was 210/160. Urea concentration was 78% of average normal. Two years previously he had been rejected for flying duties because his blood pressure was raised (amount not stated). On June 18 he was transferred to an R.A.F. hospital in England with a diagnosis of malignant hypertension.

On admission his general condition was good. The tongue was clean, pulse 100, blood pressure 260/180. The apex beat was in the fifth space, outside the mid-clavicular line with a thrusting impulse but no bruits and the artery walls were thickened. The lungs were normal. The liver, spleen and kidneys were not palpable. Examination of the central nervous system revealed nothing abnormal, the jerks were brisk. The disks were substantially as above, with commencing papilloedema of the right eye. There was defect in the left upper outer quadrant of the visual fields.

Investigations—Urine specific gravity 1020, albumin +. Urea clearance: first hour 2.26 g, Van Slyke 133%. Second hour 2.3 g, Van Slyke 129%. Blood urea 33 mg per 100 ml. Midstream specimen urine showed a moderate number of red blood cells, calcium oxalate crystals, epithelial cells and several granular casts, culture was sterile. Blood count: R.B.C., 4,800,000, haemoglobin, 94%. Excretion urography showed a slight degree of hydronephrosis of the left side, with no excretion on the right side up to 60 minutes. (See Fig. 1) Cystoscopy showed the bladder mucosa to be normal. Both ureteric orifices were normal. A catheter was passed up the right side without obstruction to 20 cm and 35 ml of sodium iodide 12% was injected. Radiographs revealed a small kidney with a marked hydronephrosis, and a diagnosis of hypoplastic kidney was made. (See Fig. 2) Despite continued rest in bed the blood pressure remained raised, the lowest recorded was on June 29, when it was 235/145.

On July 10 the right kidney was exposed through a curved loin incision. It was represented by a shell of tissue only.

and there was a fair-sized funnel shaped hydronephrosis. The kidney was removed (See Figs 3 and 4). The next day the blood pressure was 118/76. Apart from a little blood-stained urine, the patient had passed nothing since the operation. He

of urine. On the 13th the blood urea was 100 mg per 100 ml and from then onwards it gradually fell until on July 24 it was 34 mg per 100 ml, and the output and intake were normal. The blood pressure was 140/80.

On Sept 4 the headaches were much better. The sole complaint was of slight vertigo on getting up suddenly and some discomfort over the nephrectomy scar. Urine n.d., no deposit culture sterile. The blood pressure was 140/100. Ophthalmic report: There is some sheathing of the vessels where the exudates have been and a scotoma of the left eye but no signs of active retinopathy.

FIG 1—Case 2—Excretion urography, 15 minutes, showing slight degree of hydronephrosis on the left side. No excretion on the right. Calcified glands at level of transverse process of third lumbar vertebra, right.

FIG 3—Case 2. Photograph of removed kidney. There was no mechanical obstruction of the ureter.

FIG 2—Case 2. Retrograde pyelogram on right side. Tip of catheter to level of second sacral segment. Bizarre pelvis with small renal shadow.

FIG 4—Case 2. Specimen cut open. Practically no renal parenchyma left.

Case 3

LACW aged 27, with 4 years' service reported sick on July 13 1945 complaining of blurring of vision and headaches, she was admitted to hospital. For some two years she had had bilious attacks consisting of violent headaches and vomiting. The attacks lasted about 12 hours and then cleared up for a period of from two weeks to two months. The present attack had begun 7 days before and in 4 days the vision had become blurred. There was nothing in her past medical history of significance.

On examination her general condition was fair. The left vision was 6/8 the right vision 6/24. Nothing abnormal was seen in the lungs and abdomen. Neither kidney was palpable. The pulse was 100 and blood pressure 260/210. Heart

was given 2 pints (1.14 litres) of sodium sulphate, followed by glucose-saline. On July 12 he began to pass some urine. The blood urea was raised to 120 on the 11th, on the 12th it was 160 and the blood pressure 140/92. He passed 71 oz (2 litres)

sounds triple rhythm at apex, aortic second 4-4. Urine albumin faint trace, centrifuged deposit—epithelial cells only, culture sterile. Urea clearance first hour 76%, second hour, 74%. The blood urea was 39 mg per 100 ml.

Ophthalmic report. Bilateral swelling of the nerve head with scattered patches of exudate. No hemorrhages seen. The vessels appear somewhat attenuated. The fundus appearance are those of malignant hypertension.

An intravenous pyelogram revealed no function on the left side. The outline of the right kidney pelvis and calices was normal. On cystoscopy the right ureteric orifice was normal, no orifice was seen on the left side.

At operation on Aug. 8, 1945 the left loin was explored. A curved loin incision was made and the renal space opened and examined. There was no evidence of a kidney. The suprarenal gland was identified. The extraperitoneal space on the left side was explored down to the pelvis, no evidence of kidney. The wound was closed with drainage. The blood pressure on Oct. 16 was 260/200. On Oct. 31 the patient proceeded on sick leave pending discharge from the Service and died at home in the street three weeks later.

Discussion

When a new treatment or a new conception of an old condition is introduced it has at least a temporary vogue and unilateral renal disease as a cause of hypertension has been no exception. A number of papers have appeared, some with an extensive series of cases, describing hypertension relieved after nephrectomy for unilateral renal disease. On analysing these cases the majority are seen to fall into the group of mild hypertension and vice versa. It has been claimed for the treatment if the blood pressure has been reduced by as little as 20 mm Hg. It is well established that a period of complete rest in bed with appropriate dietary care, especially if accompanied by a major operation, will be followed for a time by some fall in blood pressure. Most of the published cases fall into this class. Often there has not been a clear-cut urological indication for the nephrectomy, and its performance has had only a slight temporary effect on the hypertension.

In our first case the patient had a relatively mild hypertension. On excretion urography and on direct examination excretion at cystoscopy both kidneys appeared to be functioning normally. It was therefore not considered justifiable to remove the kidney. The blood pressure fell slightly after operation, and from the time the patient was first seen it had been reduced from 215/140 to 150/120. It is not considered that this was in any way attributable to the removal of the stone from the kidney, for the fall is not more than would have been expected from the combined effect of rest in bed and a major operation.

In Case 2 there was a dramatic fall in the blood pressure after nephrectomy. In addition symptoms subsided completely and there was a remarkable clearing of advanced retinopathy. In view of this there would seem to be no doubt that the hypoplastic kidney was intimately concerned with the production of the malignant hypertension. A case of hypertension was described by Schwarz (1924) in which a hypoplastic kidney was found post mortem. Higbee (1944) reported two cases of congenital renal hypoplasia with hypertension, and both of these were relieved after nephrectomy.

In renal hyperplasia there is an immature or rudimentary kidney. It must be differentiated from renal agenesis, as in Case 3, where no kidney tissue is present, and from renal aplasia in which rudimentary kidney tissue exists without any collecting system. There is a thin rim of parenchyma which secretes urine of varying amount and quality. The calices may be normal or bizarre, and the pelvis may be hydronephrotic or quite small and bulbous in shape. The ureter is usually normal. As a general rule

the kidney is too poor in function to excrete the sufficient concentration to give a picture after an intravenous pyelogram, so that a retrograde pyelogram is necessary to show the configuration of the pelvis and calices.

The hypoplastic kidney, like all other congenital abnormalities, is liable to become infected, and this may be repeated attacks of infection or a chronic infection which both macroscopically and microscopically alter the kidney. Histologically the glomeruli are usually small and scanty, some may be hyalinized. The epithelial lining of the tubules is degenerated and it may be difficult to distinguish the appearance from the atrophic changes due to about pyelonephritis in a non-malignant form. Lowie (1934) states that almost every hypoplastic kidney contains pyramids and that nephrectomy is necessary to relieve it. In our case there was no renal symptom, nor was there anything in the post-mortem findings to suggest that there had been.

The most widely accepted explanation of the cause of hypoplasia is that the foetal kidney developed out of its development to give an immature kidney. There is in effect an end-organ malformation. The renal hypoplasia is of a nature of congenital origin, and the time of development is probably the development of the kidney.

In Case 3 the patient had a long history of hypertension and no evidence of a left kidney was found. It was therefore not justifiable to think that there might be one of renal aplasia, and if so, that the left kidney was the cause of the hypertension. After failure of treatment with the patient and his parents, the only alternative to the operation was to undertake a conservative one.

The case illustrates the need for a careful investigation in hypertension. In Case 1 the operation was successful, could only have been done by a direct approach, and have had a direct effect on the hypertension. The stone had been removed. The renal lesion was the cause of the hypertension, and the effect of the removal of the stone could be expected to be followed by only a temporary lowering of the blood pressure.

In Case 2 there was a dramatic fall in the blood pressure after the removal of the affected kidney. Such a fall in the remaining kidney was temporarily followed by a fall in blood pressure and failed to excrete for a period of 6 hours. Although the case was followed up for only a few months after which time the patient returned to Argentina, there is no doubt as to the immediate effect of the surgical treatment. In the third case the exploratory operation was purely speculative and entirely unproductive.

It would appear that unilateral renal disease is not a common cause of malignant hypertension, but it does undoubtedly occur. Investigation of the renal tract must therefore always be considered. If a unilateral disease of the kidney is found it should be treated according to accepted urological standards and operation should be performed with a view to treating the renal lesion rather than the hypertension. Treatment should not be refused because of high blood pressure or advanced cardiovascular disease. In some cases the dramatic beneficial effect of a nephrectomy will undoubtedly make justifiable surgical intervention in a poor-risk subject, and may prolong life or even effect a cure in an otherwise fatal disease.

Summary

Three cases of unilateral renal disease, including hypoplasia and agenesis associated with hypertension are described. Removal of the calculus did not materially affect the blood pressure.

Removal of the hypoplastic kidney produced a dramatic fall in blood pressure, and this remained low over the period of some months during which the patient was observed post-operatively

ARSENICAL ENCEPHALOPATHY

AN UNUSUAL CASE OCCURRING IN THE TREATMENT
OF CONGENITAL SYPHILIS

BY

G HIPPS, M.B., Ch.B.

AND

R GOLDBERG, M.B., Ch.B.

Pinderfields E.M.S. Hospital

The onset of acute cerebral symptoms occurring during, and attributable to organic arsenical therapy is a well recognized but rare clinical condition

Arsenical encephalopathy was first described by Almkvist (1911) Fischer (1912), and Kannengiesser (1912). Its incidence is given by various authorities as follows. Only 8 cases are recorded from 800,000 intravenous injections of organic arsenicals given to the British Army in the 1914-18 war (*Brit Encyc med Pract* 1939). Glaser, Imerman, and Imerman (1935) estimate the mortality secondary to neurological involvement in standard arsenical therapy as 1 in 5,398. The incidence of arsenical encephalopathy is increased in the intensive treatment of syphilis, Stokes, Beerman, and Wammock (1943) estimate the mortality in the five-day treatment of syphilis as between 1 in 200/300. Rattner (1943) describes 481 cases of syphilis treated with 0.24 g mapharside by intravenous drip given daily for 5 days in which 3 cases developed cerebral symptoms without fatal result. Craige and Sadusk (1944) report 74 cases of early syphilis in which no cerebral complications occurred following the same course of therapy. However, Goldstein, Stolman and Goldfarb (1943) give the incidence of arsenical encephalopathy as 1.3% in intensive mapharside therapy.

We should like to present a case of arsenical encephalopathy occurring in a young adult with congenital syphilis, in whom we adopted the treatment suggested, and used with much success, by Ransome, Paterson, and Gupta (1945).

Case Report

The patient, a soldier with no overseas service was admitted to this hospital on March 12, 1946, for surgical treatment of a right inguinal hernia. His age was 20, his general condition and physique were satisfactory. On examination he was found to have a left interstitial keratitis and iridocyclitis, and he gave a history of "inflammation of the eyes" for the past nine years. The Wassermann and Kahn reactions were both positive on two occasions in March, 1946. The hernia was treated successfully by radical surgery, and the following antisymphilitic therapy was adopted.

Local treatment consisted of subconjunctival injections of penicillin (500 units per ml) penicillin drops 2% atropine drops, and hot bathings. Systemic treatment was started on March 14 with 3-hourly intramuscular injections of penicillin—a total of 17 mega units being given. Arsenical therapy was begun on the 30th, 0.3 g neoarsphenamine being given twice weekly for 5 weeks, ending on May 10. A second similar course was started on July 5, the fifth injection of 0.3 g neoarsphenamine being given on the 19th. There had previously been no toxic reaction of any kind, and the eye lesions were slowly improving.

On July 20 he complained of malaise and frontal headache, which lasted until the next day, when he developed epileptiform convulsions. The aura (elicited on later questioning) consisted of "spots before the eyes". He fell on to his back, uttered a cry, and became unconscious. He then developed generalized spasticity with opisthotonos, and became deeply cyanosed. This stage lasted about a minute. It was followed by generalized clonic movements lasting 4 minutes and accompanied by severe tongue biting and incontinence of urine and faeces. Consciousness was regained after 30 minutes, but he had no recollection of the attack except for the aura. Six similar convulsions occurred during the night, and

between these he remained semicomatose and vomited profusely. He was first seen by us while he was having these fits, and thereafter was under our care.

On examination (July 21) the patient was comatose. All tendon reflexes were absent, and the abdominal reflexes could not be elicited. There was a bilateral extensor Babinski response but no ankle or knee clonus. There was no neck rigidity or Kernig's sign. He had a conjugate deviation of the eyes to the right, the right pupil reacted to light, but the left pupil was dilated under the therapeutic influence of atropine. The blood pressure was 135/90. No physical signs were found in the other systems. The urine contained no albumin, sugar or acetone bodies. There was no evidence of purpura, other skin lesions or jaundice. On lumbar puncture the CSF was under 90 mm pressure, there was no spinal block and the fluid was clear and colourless. 2 lymphocytes per cmm, 170 nig protein per 100 ml, 708 mg chloride per 100 ml, Lange curve, 0123555544, culture sterile, Wassermann reaction negative. The blood sugar was 117.6 mg and the blood urea 47.1 mg per 100 ml. The haemoglobin was 110%, RBC 6,000,000, WBC 11,600 (polymorphonuclears 71%, lymphocytes 23%, monocytes 6%). No malarial parasites were found in the blood on thick and thin films.

A provisional diagnosis of arsenical encephalopathy was made, and treatment was adopted on the lines suggested by Ransome *et al* (1945). They stress the prevention of cerebral oedema by postural nursing by keeping the patient's spine erect, repeated lumbar puncture, calcium thiosulphate, calcium gluconate, vitamin C, and adequate fluid intake. Our patient was sat up in a vertical position, given 1 ml of adrenaline (1 in 1,000) and 1 pint (568 ml) of 20% glucose by slow intravenous drip in an attempt to prevent cerebral oedema. Calcium thiosulphate 0.6 g, 10 ml of 10% calcium gluconate, and 500 mg of vitamin C were each given intravenously at 6 hourly intervals for the first day and then daily. Fluids were given *ad lib* by an intranasal Ryle's tube.

The next day (July 22) the coma gradually deepened and he became cyanosed. There were no signs of congestive heart failure, and venesection was not indicated. Continuous nasal oxygen was given. On the 23rd he was sweating profusely and in deep coma. There were slight neck rigidity and a doubtful Kernig's sign on the right. He had marked twitching of the right arm and leg and the extensor responses were still present. The temperature had risen to 104°F (40°C). One pint (568 ml) of isotonic glucose saline was given by slow intravenous drip to combat slight dehydration. Lumbar puncture was repeated. The CSF was clear and colourless, and the pressure was 90 mm. There were 7 cells per cmm (equal numbers of polymorphs and lymphocytes) and the protein was 110 mg per 100 ml, Lange curve, 0123455433, chlorides, 727.5 mg per 100 ml, culture sterile.

On the 24th the coma was much deeper, the cyanosis more marked (despite oxygen therapy), and he was breathing stertorously. The pupils were fixed to light, and there were slight neck rigidity and a bilateral slight Kernig's sign. All deep tendon reflexes were absent, and there was still a bilateral Babinski response. The temperature had risen to 105°F (40.6°C), where it remained until his death early on the 25th.

Necropsy was performed by Prof P L Sutherland who reported that the cerebral convolutions were slightly flattened and the superficial cerebral vessels congested. The ventricles of the brain contained a little blood stained fluid and the choroid plexuses were deeply congested. Numerous petechial haemorrhages were found on the visceral pleura of both lungs, and there were signs of a terminal bronchopneumonia. The liver and kidneys were normal in appearance and also histologically. Histological examination showed slight thickening of the pia mater. The vessels of the basal ganglia were unduly prominent and some appeared to be thrombosed. There was slight focal demyelination but no other evidence of cerebral lesions. Obermiller (1913) and Stuhmer (1919) state that there may be no pathological changes in arsenical encephalopathy other than cerebral congestion and oedema. The characteristic lesion, however, in this condition is multiple plugged capillaries with petechial haemorrhages and surrounding necrosis and demyelination (Russell, 1937, Strauss and Globus, 1930, Alpers, 1928).

Differential Diagnosis

We consider this case to be one of arsenical encephalopathy for the following reasons. There was no personal or family history of epilepsy, there was no previous evidence of cerebral syphilis, and it is very unlikely that he would develop the first signs of this after starting treatment with penicillin and arsenic and in the presence of a negative CSF Wassermann reaction. The blood pressure and blood urea were normal and there was no albuminuria, thus eliminating hypertensive encephalopathy and uraemia. The blood sugar was normal and there was no glycosuria or acetonuria, ruling out diabetic coma or spontaneous hypoglycaemia. The patient did not have any other

Reviews

CHEMISTRY OF MICRO-ORGANISMS

An Introduction to Bacteriological Chemistry By C. G. Anderson Ph.D. Second edition (Pp 500 20s) Edinburgh E and S Livingstone 1946

The Society for General Microbiology, the youngest association of bacteriologists in this country, has since its inauguration in the beginning of 1945 attained a membership of over 550, comprising workers in the fields of medical, veterinary, agricultural, and industrial bacteriology. At a recent symposium it was made abundantly clear that these workers, attacking their various problems from their own standpoints, were inspired by a common desire for fundamental knowledge of the mechanisms by which bacteria and the lower fungi live and produce their effects. Much of this knowledge has been obtained by the study of bacterial enzymes and fermentation products, of factors essential to the growth of bacteria, and of components obtained from organisms by chemical fractionation. The advances of the last ten years have been striking, and it is therefore an appropriate time for the appearance of a second edition of this useful volume.

The 500 pages of the book represent an increase of some 220 pages on the first edition, an increase largely accounted for by new chapters dealing with antibiotics and chemotherapy and by considerable expansion of those sections describing the advances in enzyme chemistry and bacterial nutrition which have made possible a rational approach to the practical problems of disinfection and treatment. Part I is devoted to a general account of the physicochemical properties of bacteria and fungi. Part II, the main section of the book, on bacterial metabolism, includes in addition to the work already mentioned descriptions of the mechanisms and products of fermentation and accounts of the proteins, polysaccharides, lipoids, and pigments of micro-organisms. Part III contains a short account of certain aspects of immunochemistry. In place of a detailed bibliography the author gives at the end of each chapter references to selected monographs and reviews. This book, carefully planned and clearly printed, succeeds well in its object of presenting a concise survey of a widening field. It is likely to find a place close to the hand of most bacteriologists.

JUVENILE SKIN DISEASE

Skin Diseases in Children By George M. MacKee, M.D., and Anthony C. Cipollaro, M.D. Second edition, revised and enlarged. With contributed chapters (Pp 448, illustrated 37s 6d) London Hamish Hamilton Medical Books

Although revised and enlarged this handbook on skin diseases in children preserves its original characteristics. Most of the usually described dermatoses are included, and there is nothing much in the text to distinguish it from a textbook of skin diseases not limited to the first decade or so of life. The chief omissions are senile pruritus and the cutaneous epitheliomata, which, while prone to attack the ageing dermis, are hardly known to affect children. The authors have, however, found room for a brief notice of the sarcomata, which are not quite so rare at this epoch. But on the whole there is very little real distinction to be drawn between the dermatoses of childhood and those of more advanced years, and it is rather an artificial classification to try to separate them off from the main body of cutaneous disease. However, if we accept the authors' objectives we must admit that they have produced once more a good account of their subject.

As is proper in a book devoted to juvenile skin disease a great deal of space is taken up by the discussion of atopic dermatitis and eczema in childhood. To a certain extent the authors appear to be obsessed by patch tests, but it seems difficult to understand their importance when it is stated that a positive skin test does not necessarily prove that a particular atoiden is the causal agent while, as is well known, a negative reaction does not exclude it. Another disease, acne vulgaris, the bugbear of adolescence, is also fully dealt with. Much importance is attached to restriction of diet, and after reading the formidable list of foods which are to be avoided by acne patients, one

may feel the consolation that acne ought to be becoming rare in this country, for the list comprises practically all the articles of diet which, owing to the war and its consequences, are regretably scarce to day.

We must once more comment on the excellence of the illustrations—almost all photographic reproductions. There is no doubt of the advance in photographic technique in the last twenty years, and it is fully reflected in the improved illustrations of many medical works, perhaps dermatological subjects have profited more than other branches of the art. In this particular work there is only one coloured plate—the frontispiece—and it cannot be said that it compares favourably with the monochromes. The quality of light and shade and modelling obtained in the ordinary straight photograph is still superior to that in reproductions in colour.

NEUROLOGICAL SURGERY

The Principles of Neurological Surgery By Loyal Davis, M.S. M.D. Third edition, thoroughly revised (Pp 540, illustrated 37s 6d) London Henry Kimpton 1946

It is already well known that this book presents to the student or to the tyro in neurosurgery all that he needs to know of a rather specialized subject, and moreover that it makes enjoyable reading. When looking through the third edition, therefore, we turn to subjects upon which views have changed or new knowledge has been added in recent years, and we find the same well-balanced, level-headed summing up of the opinions and practices at the present day, and the same nice judgment about the amount that the student needs to know in order to enable him to understand the processes of disease and to recognize the cases which demand expert attention, without making any attempt to turn him into an expert or to force upon him the over-enthusiasm of the specialist. These remarks apply particularly to the sections on intracranial abscess, aural vertigo, spinal cord injury, herniation of the intervertebral disks, peripheral nerve injuries, and essential hypertension.

The surgery of the nervous system terrifies many a student, because he is given to understand that the field is so vast and the problems are so intricate that it is a hopeless task—he is defeated before he attempts to attack it. This book, which includes within its 540 pages the essentials of the anatomy, physiology, and surgery not only of the central nervous system but of the peripheral and autonomic nervous systems also should give him hope and encouragement in making the attempt, and will certainly give him a grasp of the subject, if not an active interest in it, as the reward for his study of its contents. The work remains a splendid testimony to the author's wide experience, sound judgment, and literary skill.

HANDBOOK ON SOCIAL WELFARE

Health and Social Welfare (Pp 528 25s) London and New York Todd Publishing Co., Ltd. British distributors George G. Harrap and Co., Ltd.

The publishers say they are more confident than ever that this, the third issue of their handbook, "adequately fills a very real need in the equipment of all engaged in any of the many branches of social service." There is no doubt that the number of potential users of such a book is rapidly growing, and they are not likely to be disappointed when they turn to it for help. Section 5, Unofficial Statements, of this hand- somely produced volume begins with the Association of Occupational Therapists and ends with the "YWCA." Full lists under the several Ministries are given of officially appointed committees and reports. There is a very useful section on careers in health and social welfare, a directory of organizations interested, a section on statistical tables, and finally a 'Who's Who' in health and social welfare. Much out of the way information is given which otherwise would have to be sought at the expense of considerable time and trouble.

Lord Horder, who is the advisory editor, asks in a foreword for the help of readers in making the book more useful in future, and it is with this intention that the following suggestions are made, based on many dips into its pages. In the list of periodicals devoted to the subject there is no mention of the *National Insurance Gazette* which for many years has been the only journal devoted to the problems of the administrators of national health insurance. The Cremation Society

is not mentioned. Though there are many references to societies and institutions for the deaf and dumb there is no help given to those who are asked by deaf people how to get honest and disinterested advice on hearing aids. It would be useful to have if only in a line some indication of the scope of some of the lesser known bodies that are listed—for example the British Health Freedom Society, the Health Practitioners' Association, and the London Health Centre.

There is a valuable summary of health and social welfare legislation and policy written in a severely objective manner and with artistic use of meiosis. In the reference to the new National Health Service it is said that "much of its content and direction will in future be determined by regulations" and in the section on careers the undoubtedly safe statement is made that "the public service will absorb an increasing number of doctors when the Government's national health policy is implemented."

We give this handbook a cordial welcome for it seems to fill a gap in the long line of reference books. Time alone will show whether the faith of its publishers is shared by those whose service it is offered or how far the promise of State control will diminish the number of voluntary bodies whose objects fill so much of the book.

ELECTRICAL CONVULSION TREATMENT

L'Electro Choc et la Psycho-Physiologie. By Jean D. L. (Pp. 169. 250 francs). Paris: Masson and Co.

The author attempts to formulate a neuro-physiological theory of the action of electrical convulsion treatment on human physiological processes in health and disease. He begins by discussing the clinical features of manic melancholia and hebephrenia and their physiological in effect but not formal attention on the hypothalamus as the main centre of disturbance of function. All the effects of electrically induced convulsions on consciousness, on reticulate function, and on the vagal-sympathetic balance are then discussed. Small numbers of patients have been studied experimentally in an intensive way, and the results of the findings are to show that after convulsions there are changes in blood picture, gastric acidity in the concentration in the blood of water, protein, total lipids, calcium and phosphorus, and also in the alkali reserve, leucocytosis, and changes in the electroencephalogram. The changes vary with the time of observation after the convulsion, and are interpreted as showing first a vagal stimulation, succeeded and overborne by powerful sympathetic excitation which is itself followed by a mild but more prolonged vagal effect. The physiological changes are then related theoretically to the therapeutic effects obtained in the convulsion treatment of the affective and schizophrenic psychoses.

The book is heavy reading, since it is written in a discursive style and the author at no point presents his findings and arguments in summarized and self-contained form without their being overladen with discussion. The discussion is, however, often of great interest. There is a wealth of clinical as well as experimental observation, and extensive references to the very large literature relevant to the subject. Much that is said is controversial, and no doubt some of the views expressed will demand revision in the light of later findings. Nevertheless the book is important as the first attempt at a synthesis of the present state of our knowledge of the pathology and therapeutics of the functional psychoses.

The handbook for students and practitioners entitled *Pulmonary Tuberculosis* by Drs R. Y. KERR and B. G. RIGGS was favourably noticed in our issue of June 2, 1945. In preparing a second edition (Edinburgh: P. and S. Livingstone, 1946) the authors have refrained from enlarging the scope of their work, and it can be recommended once again as a concise and up-to-date account of the subject. The increasing use of pneumopercutaneous as a method of treatment has called for more extensive reference to that procedure, and the section on BCG has been expanded in view of the latest reports from Scandinavia and the influential demand for its trial in Britain. The passage into law of the Disabled Persons (Employment) Act, 1944, has been a landmark in the history of rehabilitation, and the provisions of the Act are explained.

BOOKS RECEIVED

(Reviews in this section are by the Editor of the Journal, unless otherwise stated.)

The Common Cold and How to Fight It. By N. D. FAHNEY, M.D. (Pp. 116. 5s. 6d.). London: Medical Books, 1946.

An excellent book for the lay reader by an American ENT specialist, of interest to general practitioners.

Contraception. By M. C. S. S. (D.S. 54th ed.). Revised. (Pp. 112. 5s. 6d.). London: Lippincott, 1946.

The author discusses the various methods of contraception, and the ethical and social aspects of the problem.

The Development of Infantile Anorexia. By P. S. A. D. (Pp. 112. 5s. 6d.). London: The Medical Book Co., 1946.

A book of interest to the general practitioner, and a valuable contribution to the literature of infantile anorexia.

Clinical Practice in Infectious Diseases. By F. H. F. (Pp. 112. 5s. 6d.). London: Lippincott, 1946.

This book is a practical guide to the treatment of infectious diseases, and is of great value to the general practitioner.

Diseases of the Nervous System. By F. H. F. (Pp. 112. 5s. 6d.). London: Lippincott, 1946.

A book of interest to the general practitioner, and a valuable contribution to the literature of nervous diseases.

At Home with Ischemic Heart Disease. By W. H. (Pp. 112. 5s. 6d.). London: Lippincott, 1946.

An excellent book for the lay reader, and of interest to general practitioners.

A Practical Handbook of Pathology for Students and Nurses. By M. A. (Pp. 112. 5s. 6d.). London: Lippincott, 1946.

A book of interest to students and nurses, and a valuable contribution to the literature of pathology.

The Animal Chemistry of the Digestive System. By F. H. F. (Pp. 112. 5s. 6d.). London: Lippincott, 1946.

A book of interest to the general practitioner, and a valuable contribution to the literature of animal chemistry.

First Baby. By W. H. (Pp. 112. 5s. 6d.). London: Lippincott, 1946.

A book of interest to the general practitioner, and a valuable contribution to the literature of obstetrics.

Burns, Scalds, and Frostbite. By G. S. (Pp. 112. 5s. 6d.). London: Lippincott, 1946.

An excellent book for the lay reader, and of interest to general practitioners.

Philosophy and Medicine in Ancient Greece. By W. H. (Pp. 112. 5s. 6d.). London: Lippincott, 1946.

A book of interest to the general practitioner, and a valuable contribution to the literature of philosophy and medicine.

Characterization of Organic Compounds. By F. H. F. (Pp. 112. 5s. 6d.). London: Lippincott, 1946.

A book of interest to the general practitioner, and a valuable contribution to the literature of organic chemistry.

Anesthetic Methods. By G. K. (Pp. 112. 5s. 6d.). London: Lippincott, 1946.

An introductory text book on anesthetic methods, and of interest to general practitioners.

Infectious Diseases. By A. B. (Pp. 112. 5s. 6d.). London: Lippincott, 1946.

An account of the various infectious diseases, and of interest to general practitioners.

RETURN TO NORMAL

Because of the fuel crisis we were prevented from issuing the last two numbers of the *BMJ* in the normal manner. The result has been a severe dislocation of work. The publication of many articles and of other matter has had to be postponed. An attempt will be made during the next few issues of the *Journal* to make good the loss of space incurred, but even then many correspondents will have to be disappointed. We are confident, however, that readers will appreciate the difficult position in which the *Journal* has been placed and realize that the return to normal will have to be a gradual process.

When it was found to be impossible to make alternative arrangements for printing the *Journal* in parts of the country not at first brought under the fuel ban the possibility was looked into of bringing out the *Journal* in duplicated form. The Secretary of the BMA put at the disposal of the Editor the services of his staff and duplicating machines. By restricting the size of the last two issues of the *BMJ* to two sides of a foolscap sheet it was possible to "print" the normal run of approximately 62,000 copies. A draughtsman in the Finance Department cut the title and the *Journal* device on the stencils. Our two pennican issues were, in fact, entirely a home product and were brought out by the co-operative effort of all departments in BMA House. As the electricity was cut off from the addressograph machines a treadle mechanism was brought into use and the 62,000 envelopes addressed by human foot-power. So the two pennican *BMJs* came out without the consumption of a watt of electricity. In spite of this, as readers by now probably know, exception was taken in certain quarters to the issue of the *BMJ* in any shape or form, even though no fuel and power were used. This extraordinary state of affairs was a symptom of a social malaise which those responsible for producing the *Journal* felt it their duty to resist. *Science To-day*, the *Isis*, and the *Liberal News* were apparently the only other journals which appreciated the fact that there was no legal bar on the production of a journal. The fact that the rest of the periodical Press succumbed weakly to what was nothing more nor less than temporary censorship seems to suggest that this country has lost some of that initiative and enterprise supposed to be characteristic of the British people. The queue habit seems to have got a firm grip upon us, and the readiness with which editors and proprietors of various journals lined up in the queue shows a strange lack of resourcefulness in a profession in which this quality is usually in high demand. We would like to thank those readers who have appreciated the fact that the

Journal was not bluffed into inaction. We publish in this week's Correspondence pages a few of the many letters we have received.

PREFRONTAL LEUCOTOMY

The Board of Control report¹ on prefrontal leucotomy marks a stage forward in the establishment of this method of treatment in its proper place in psychiatry. The report gives a comprehensive survey of the results of treatment at many centres, as judged by many observers and passionately discussed. Many difficulties, in shortage of staff and otherwise, had to be contended with and rob the factual data of some of their value, for it is clear that while some centres sent in detailed accounts of individual patients others reported only in the baldest terms. An inquiry form was issued to every county and borough mental hospital and registered hospital, and to most of the licensed houses. Completed returns were received from all the hospitals which had undertaken the treatment up to the end of 1944. It is of interest that these included one-third of the total of 97 mental hospitals and 6 of the 13 registered hospitals, this shows how widespread the use of the method has already become.

The report analyses the results in 1,000 patients, 348 males and 652 females. Of these the largest single group were the schizophrenics—599 cases. It was not possible to subdivide these by diagnosis into paranoid, catatonic, and hebephrenic types, which would have been a matter of great interest. After the operation approximately 5% of them died, and 25% could be discharged from hospital, the others had to remain in hospital, 36% of them in an improved state. Of the whole group over 60% could be regarded as improved, and 16% were counted as recovered. There was a small relapse rate, amounting to no more than 4% of the total material. Considering the gravity of the disability in these patients, mostly chronic cases in which no other method of treatment offered any hope at all, the results are encouraging. They were still better in the 250 manic-depressive patients, in whose number an unknown proportion of involuntal melancholics are included. Of them 8% died, but nearly 80% were improved. Over half could be discharged from hospital and 45% were regarded as recovered. A miscellany of other conditions had also been treated, including epilepsy, mental defect, and post-encephalitic states. In them the results were less striking, except in the obsessional neuroses, of the 29 obsessional patients 2 died, 1 failed to improve, and 23 were discharged from hospital, 17 of them being counted recovered. These findings support the results observed by many individual workers in the past. Of all chronic and incapacitating psychiatric conditions the severe obsessional neuroses respond best to leucotomy, the affective psychoses next best, and the schizophrenias though favourably on the whole, least well.

There are some interesting correlations with age and sex. On the whole the men did rather better than the women in both schizophrenic and manic-depressive groups, and the

¹ *Prefrontal Leucotomy in 1 000 Cases*. Board of Control (England and Wales) H.M.S.O. London 1946.

older age-groups had better discharge rates than the younger. In both the two large diagnostic groups the discharge rates for men are strikingly higher than for women over the age of 35. The duration of the illness is also shown to be of prognostic importance. The proportion of patients discharged recovered or improved after leucotomy in the first two years of the illness is very much higher than when the operation is performed later on. In the schizophrenics the rate drops from 56% and 47% in the first two years to 20% in the next three, in the manic-depressive group the rate falls off much more gradually from 74% and 59% to 47%. However, both in the schizophrenics and manic-depressives there is a discharged improved rate of about 10% even in patients who have been ill for ten or twenty years. These figures show that there is much that is still to be learned about the indications for treatment in chronic psychotic conditions.

The report goes on to give an analysis of the results considered in terms of social behaviour and symptoms. Under the first heading a considerable proportion of patients were classified as citizens—i.e., earning their living, managing their homes, or otherwise taking a normal place in the community. For the grave disabilities which have been treated by leucotomy this represents a high standard of recovery. Nevertheless 24% of all patients together reached this standard—16% of the schizophrenics, 43% of the manic-depressives, and 55% of the obsessional. High standards of improvement were obtained in respect of violence, difficult behaviour, and working habits, and in only 1% of the whole thousand could the symptoms be called worse after than before the operation. Some symptoms are much more responsive to treatment than others, suicidal tendencies, depression, and agitation were abolished in over 70%, hallucinations, delusions, and excitement in only 20-37%. The occurrence of new symptoms after operation was infrequent, post-operative epilepsy was seen in only 3%. An attempt is made to answer the question whether there are changes in personality after the operation, but the data are insufficient.

The conclusions drawn are that the operation is a simple one for the patient, and the death rate not high when the seriousness of established mental disorder is taken into account. There is remarkable improvement in behaviour in a large percentage of severe cases with poor prognosis. Further study is required to decide whether the results are achieved at the cost of the loss of some finer mental qualities. The operation should be carried out only after careful consideration of each individual case by experienced psychiatrists.

The benefits which result from leucotomy in successful cases underline our present ignorance of principles of selection. Patients have not been generally as closely studied both before and after operation as could be desired, and it is hoped that opportunities in this way will be better used in future. At least two intensive surveys are now proceeding which should add much to our knowledge in this field. But it would be unfair not to admit that the substantial proportion of chronic and otherwise incurable patients whom it has proved possible to discharge from hospital after leucotomy means a great advance in treatment.

GROUNDNUTS IN EAST AFRICA

The present deficiency of fats in the national dietary exceeds 1,000,000 tons a year. The problem is to find fresh sources of supply to make this good. The Government have therefore launched a bold scheme for producing groundnuts in East and Central Africa¹ on 3,250,000 acres of barren land in Tanganyika, Northern Rhodesia, and Kenya. This will bring benefit to the inhabitants of this vast area as well as to Britain. The African economy is based primarily on subsistence agriculture conducted by the primitive method of the hand-hoe. The production by these primitive methods is probably already on the decline, and the welfare of Africans will depend upon their emergence from subsistence agriculture to modern methods made possible only by capitalized development. British and African needs can be met by this long-sighted scheme of the present Government. But unless the urgent problems of health and disease are satisfactorily solved the scheme will not work. Hospitals, village health centres and community health centres are being planned for the benefit of the African native. It is to be hoped that among the many experts consulted the Government has not overlooked the anthropologist, because any system based on Western medicine will come up against the invisible and powerful obstacles provided by the African natives' primitive methods of thinking, as expressed in tribal medicine. Apart from such diseases as leprosy, syphilis, and malaria there is the forbidding aspect of trypanosomiasis, for the area to be developed is the haunt of the tsetse fly. The clearing of an enormous area of uninhabited bush is in itself a stupendous task, but it becomes still more complicated when that bush is uninhabited because it is the haunt of tsetse flies infected with trypanosomiasis. If workers are to be brought in to cultivate groundnuts then it is essential first to eradicate the tsetse fly. That such can in fact be done has been amply demonstrated at Pogg Tamale in the Gold Coast and on an even larger scale in the Anchau corridor in Northern Nigeria. In what has come to be known as the Anchau experiment sufficient time was available for preliminary examinations and surveys, the object being not only to clear tsetses from the area but to shift whole populations and at the same time rehabilitate them. Operations were begun in 1935 and only now are drawing to their close. In Tanganyika time presses. Yet here, also, expert knowledge is absolutely essential if correct measures are to be taken. Rapidity of action is one necessity in eradicating tsetse flies. Tsetses cannot live far from water. In the dry season they breed only in the bush which fringes rivers and streams, but during the rains they spread out from the river banks, often for considerable distances. When the dry season returns they retreat to the fringing forest, except for a few flies which continue to live in isolated thickets in the so-called hard-pan depressions, where there is enough moisture to provide the required microclimate. The work of clearing bush must necessarily be accomplished in the dry season, and the cut wood must be burnt quickly, for if stacks of brushwood

¹ A Plan for the Mechanized Production of Groundnuts in East and Central Africa, H.M.S.O., Cmd 7030 Feb. 1947 1s net

remain till the rains descend ideal breeding-places are provided. Then, too, expert botanical knowledge must be at hand to determine which species of trees must be cut and which may be allowed to remain. In East Africa the tsetse *Glossina morsitans*, for instance, breeds in close association with *Isoberrhina-Brachystugia* woodland (Nash²), but *G. swynnertonii* and *G. palpalis* have different habitats, and selective bush clearing may fail to eliminate *G. swynnertonii* (Bax³). If too much vegetation is removed from the banks of rivers and streams tropical downpours may all too readily cause extensive scouring and soil erosion.

Once tsetses have been eliminated in the selected areas in Tanganyika new villages will have to be built to house the groundnut farmers, new wells will have to be sunk, and new farms created in which mixed farming can be carried on, for adequate diet is essential if the African is to develop his full capacity for work. Fortunately, even though conditions in East and West Africa are not identical, in the Anchau experiment a large-scale model is available to indicate what must be aimed at. As the scheme is put into operation there should be many opportunities for intensive and valuable research. It should be possible, for instance, to determine whether pentamidine is really of value as a prophylactic against sleeping-sickness and to ascertain the best tsetse repellent for use by those engaged in clearing infested bush. Pyrethrins^{4,5} and indalone⁶ are known to have some action in deterring that most persistent of insects, the tsetse fly, from biting, but further investigations are required to ascertain how far the action of these repellents is destroyed by sweating and exposure to sunlight.

The whole Tanganyika project entails the application of preventive tropical medicine on a scale never before attempted in Africa. If proper precautions are taken the outcome of the project should be to provide essential fats and oils for starving Europe and to ensure for many thousands of Africans a better and a healthier way of life.

THE HEART AND BERIBERI

A recent article entitled "Cœur et Béri-Béri," by Dr Jean Casanova,⁷ is probably the most complete mass observation of this condition that has been made. The disease appeared in epidemic form among black Senegalese troops stationed on the Tunisian and Tripolitanian frontier in 1940. Their diet was poor, their work heavy, and more than 300 cases came under observation. It was found in general that cardiac cases with frank oedema, and those partially cured or relapsed oedematous patients with asthenia, nervous symptoms, and mild cardiac disorders only, responded rapidly and uniformly to vitamin B therapy. On the other hand, cases that from the time they were first seen were considered to be of the "dry" type showed marked cardiac lesions which did not respond to therapy and were usually

fatal. It was uncertain whether this group represented relapses from previous oedematous cases or whether they were affected by some other vitamin deficiency in addition to that of B₁, unfortunately it was impossible to carry out extensive biochemical examinations.

Sporadic cases with cardiac symptoms similar to those Casanova describes have been recorded by a number of observers but it has not always been possible definitely to determine that the condition was beriberi, and the recognition of this large group arising in the middle of an epidemic would appear to be a clinical observation of the first importance. It seems hardly correct to label them as the "dry" form, for peripheral neuritis, for example, was absent. A better term would appear to be "subacute cardiac" beriberi. There is considerable evidence that they are really cases of severe cardiac damage in patients suffering from the disease in a chronic subacute form in which the brunt of the attack is borne by the heart muscle. Casanova's investigations were carried out on patients of this last group. Clinically, nervous symptoms were rare, and oedema when it occurred was confined to the tibial region. There was no marked change in the general appearance, and the patients usually complained of lack of appetite and a sense of constriction in the chest. Examination revealed violent and striking pulsation in the epigastric region, praecordium, and neck, a Corrigan type of pulse, tachycardia aggravated by the slightest effort, and a very poor exercise tolerance. The blood pressure was raised in proportion to the rate of the heart beat. Radiologically there was the gross right-sided cardiac enlargement which takes place in this condition, and very striking pulsation in the pulmonary conus and the aorta.

More important, however, were the results of the electrocardiographic examinations. There was no absolute uniformity about these tracings, but, generally speaking, the P waves were accentuated and sometimes distorted, the P-Q interval was increased, and there was a widening of the QRS complex and various inconstant alterations in the T wave. The general indications were of a sinus tachycardia and marked impairment and delay in the passage of the cardiac impulse through the ventricles. The ventricular contractions were often asynchronous. Although the systolic phase is always lengthened in consequence of these changes, the pulse remains rapid by reason of a shortened diastole. The response to digitalis of hearts of this type is peculiar in that administration of the drug increases the pulse rate—a finding which was regarded by Casanova as diagnostic. It was also noted that in two cases which had jaundice the pulse rate was temporarily lowered and the patient improved, but when the jaundice disappeared rapid deterioration set in and death followed. The biochemical investigations were scanty, but in the few cases examined the serum albumin was remarkably high while the globulin was approximately normal. No detailed post-mortem notes are included in this paper.

A recent paper by Allibone and Baar⁸ describes a fatal relapsing case of beriberi occurring in a child in this country. The main clinical features were again noted in the heart and at necropsy the heart muscle showed "such changes as would be expected if a typically acute beriberi heart as described by Wenckebach⁹ were to survive for a longer period." Just as in Casanova's cases, there was resistance to vitamin therapy, sinus tachycardia, large distorted P waves (but in this case the P-Q interval fell within normal limits) and the T wave was absent. The serum albumin was actually lowered, however, and it is clear that

more information is needed on this point. The post-mortem findings are described in detail, with some excellent photographs, and it is interesting to note that in this case there was an aneurysm of the pulmonary conus, which contained a thrombus. Very full references to the literature are given at the end of this article.

These two papers should be read in full. They show with the greatest clarity how conditions associated with deficiency of the vitamin B complex may produce myocardial changes that are irreversible despite strenuous therapy, and they will prompt speculation as to how often obscure cases of cardiac enlargement and failure may arise from similar causes.

PATHOLOGY OF SUDDEN DEATH

The dramatic exit, while arousing our greatest sympathy for those so suddenly bereaved, is of considerable scientific and medico-legal interest, and it is rarely fully explained by morbid anatomy. Moreover, it may be preventable. To the physician sudden death usually implies an abrupt affair, to the coroner it includes any death within 24 hours of a person's being taken ill unexpectedly. Published studies of the mechanisms involved, and of the underlying diseases responsible, are scanty and usually suffer from lack of adequate clinical data. A recent study of the morbid anatomy of 500 cases of "sudden heart death" by Munk¹ is no exception to this rule. Selection was unavoidable and tended to exclude women and very old people. Figures for sex and age incidence are therefore unreliable, but valuable facts are given concerning sudden death in relatively young and middle-aged men. The term 'sudden death' is not defined, but appears to be used in the wider sense of the coroner.

In the total series of 411 men and 89 women ischaemic heart disease was considered responsible for the death of 79.2%, syphilitic aortitis with stenosis of the coronary ostia for 11%, and valvular lesions for 3.6%. Pulmonary embolism, for which Barnes² held to blame for 2 to 5% of all deaths in hospital, was not mentioned, but may have been considered "non-cardiac". Dissecting aneurysm and spontaneous rupture of the aorta may have been excluded for the same reason. No case of diphtheritic carditis was seen.

On the whole the facts reported confirm what is already well established, though perhaps not widely known. Thus of 141 cases of coronary thrombosis 37 had neither myocardial infarction nor fibrosis, and 60 had fibrosis only. Of 74 cases with myocardial infarction, coronary thrombosis occurred in only 44. Clawson³ recorded 281 cases of myocardial infarction of which 64 had no coronary thrombosis. Thus a clinical and electrocardiographic diagnosis of coronary thrombosis cannot be more than a good guess and should be discarded in favour of myocardial infarction. That there was sudden death in 79 cases (19.9%) of ischaemic heart disease without coronary thrombosis, myocardial infarction, or fibrosis, and in 142 cases (35.8%) with fibrosis only, is of greater interest, for this comprises more than half the group and is contrary to hospital experience. The recorded heart-weights of these cases (245-880 g, average 450 g) indicate that many were hypertensive as well. Clinical studies, according to Riseman and Brown,⁴ usually reveal hypertension in about 50% of cases of ischaemic heart disease. That pure hypertensive heart disease very rarely terminates abruptly (6 out of 500 cases) is of medico-legal importance. The high

incidence of aortic stenosis among patients with V.D.H. dying suddenly (10 out of 18) is in harmony with general opinion.

Perhaps the most important fact which emerges from these observations is that sudden death in the natural course of heart disease is due to myocardial ischaemia in over 92% of cases, usually from coronary atherosclerosis (79.2%), sometimes from syphilitic stenosis of the coronary ostia (11%), and occasionally from aortic stenosis (2%). This fact is not new but is emphasized. Death took place on exertion in a third, quietly at home in a third, and while performing gentle social activities in a third.

The mechanism is assumed to be ventricular fibrillation or asystole. As quinidine has been shown by Wegria and Nickerson⁵ to protect the dog's ventricles from ventricular fibrillation, the prophylactic use of this drug in the types of heart disease mentioned should be considered.

NICOTINE AND FERTILITY

There are now in the literature several papers which show that nicotine when administered daily to animals over a period has some effect on fertility, as indicated by the occurrence of abortion, of premature births, of stillbirths, and of a decrease in the number of young born. There are also a good many reports on human subjects, though these are mostly less convincing than that of Phillips⁶ who established a relation between smoking and immotility of spermatozoa in a young man. When he stopped smoking motile sperms appeared, when he resumed smoking motility disappeared when he stopped again motile sperms appeared again.

Thienes, Lombard, and their colleagues⁷ have now described some experiments in which they have measured the fertility of rats injected daily with nicotine in comparison with that of control rats injected daily with saline. There were three experiments in which, taking the three together, 92 pairs of control rats were compared with 83 pairs injected with nicotine. Of the control pairs only 17% were not fertile over a period of nearly 12 months, while of the pairs injected with nicotine as many as 33% were not fertile. Not only was the percentage of non-fertile rats about twice as great in those injected with nicotine as among the controls, but the number of progeny was much less. Each control pair had on the average 28 young in the experimental period, while each pair receiving nicotine had only 19 young. The doses of nicotine were 2.0 to 2.5 mg per kg given twice a day, and were nearly as large as could be given without causing convulsions. Lombard⁸ has pointed out that the relative daily dose injected into rats in these experiments would correspond to the maximum amount of nicotine which could be absorbed from 40 cigarettes. Lombard's estimate of the amount of nicotine absorbed seems excessive, it would be difficult for the most determined inhaler to take in 7 mg from one cigarette, and there is good reason to believe that a cigarette normally yields about one-tenth of this.⁹ But Lombard assumes that the rat and man are equally sensitive, and again there is good reason to believe that man is much more sensitive to nicotine than the rat.¹⁰ In the effect of nicotine on the hypothalamus, man is from 100 to 200 times more sensitive than the rat. Here then is an important addition to the evidence that smoking is far from being a harmless habit.

HOSPITAL PLANNING AT OXFORD

A Planning Committee of the Oxford and District Joint Hospitals Board has worked out a programme of area hospital planning. Sir Farquhar Buzzard presided over the committee until his death early last year, and since then Prof G E Gask has been chairman of a committee of fourteen, half of whom are medical men. The planned area covers the city of Oxford and almost the whole county, with parts of Berkshire and Buckinghamshire a total population of about 300,000. It is considered that the number of beds for acute sick cases should be 5 per 1,000 population with half this number for chronic sick (the committee prefers to call them long-stay cases), and smaller numbers for cases of infectious disease, tuberculosis, convalescence, and maternity, the total—leaving out mental hospitals—providing for 1% of the population.

In considering the acute sick, allowance has to be made for the special position of Oxford as a teaching centre. The Radcliffe Infirmary, the Wingfield-Morris Orthopaedic Hospital and the Oxford Eye Hospital receive patients from a wide area and Oxford has to provide certain highly specialized services for the region as a whole. It is estimated that 453 new beds are needed in Oxford for the acute sick. At present about half the beds in the ten cottage hospitals in the district are used for the treatment of acute sick, but the committee is opposed to their continued allocation for that purpose and makes suggestions for using them to greater advantage.

The "Long-stay" Cases

All but a small minority of chronic sick or long-stay cases are accommodated in public assistance institutions, and the committee is unanimous in its opinion that these institutions are unsuitable for the nursing of such cases and that the accommodation they afford should be omitted from any summary of available resources. This means that some 700 beds in Oxford and Banbury and the surrounding areas are needed for such cases, all of them to be provided eventually in new buildings, some in new wards or blocks attached to general hospitals, and all of them in close association with such hospitals. Public assistance institutions are judged unsuitable also for maternity cases, for which at present they provide 43 beds, and the establishment of over 300 maternity beds is recommended distributed between the key or primary centre at the Radcliffe Infirmary, the secondary centre at Horton General Hospital, Banbury, and a number of local centres at Abingdon, Didcot, and elsewhere. Sufficient beds for infectious cases already exist and no observations are made on accommodation for the tuberculous because a joint committee of the local authorities concerned is dealing with the problem.

The *Hospital Survey* published last year, called for the reconstruction of most of the Radcliffe Infirmary, and stated that the total number of beds needed for the Oxford hospital could not be provided on the Radcliffe site (*British Medical Journal* 1946, 1, 770). Since the *Survey* was published the city council has added to the hospital services of Oxford by acquiring from the Ministry of Health the Churchill Hospital with accommodation for 312 patients, but it consists of temporary buildings with only a limited life.

The Future of the Radcliffe

The short-term policy recommended in this programme is to continue the alterations at the Churchill Hospital to enable it and the Radcliffe Infirmary to work at full capacity until the new hospital or hospitals can be built. The long-term policy is to build a new hospital at Headington, which would belong to the Radcliffe Infirmary. The future use of the Radcliffe site cannot be determined until the hospital policy of the Ministry of Health and the requirements of the medical school at Oxford are known. It is considered that a maternity unit of 50 to 100 beds should be built on the Manor House site, Headington, where also should be provided a block of about 100 beds for the chronic sick who require further investigation and treatment. There should be on the same site or on the Wingfield-Morris Orthopaedic Hospital site an additional 100 beds for orthopaedic cases. Another requirement is the building of a new eye hospital, the existing one being inadequate and unsuitable. The Churchill Hospital should be retained as an integral part of the

medical services of the area, perhaps for the chronic sick. The Horton general hospital at Banbury should be developed and a maternity unit and, eventually, a block for the chronic sick should be built there.

It is recommended that the cottage hospitals in the area be used for the observation of difficult cases, the nursing of patients under the care of their own general practitioners and the treatment of minor casualties, and they might be developed as centres of all the medical activities in their districts including maternity and child welfare and school clinics. Each of them should have a large room for clinical conferences at which senior members of the parent hospital staff would attend at stated intervals and so relieve general practitioners from professional isolation.

On the general question of staffing, one whole time medical officer (or his equivalent in part-time officers) is recommended for every 20 beds, or 50 for a 1,000 bed hospital.

H M PRISONS IN THE WAR YEARS

REPORT FOR 1942-4

One of the most encouraging features of the latest report of the Prison Commissioners¹ is the account it gives of the revival and growth during the war of the psychiatric activities of the prison medical service. The Medical Commissioner, Dr J C W Methven, reports a further considerable increase in the number of accused persons remanded to prison for mental observation. He again appeals to magistrates and their clerks to send the fullest particulars of prisoners, for the better the background knowledge of the case the lighter the work of the prison medical officer. From a medical point of view the most important event recorded in this report was the reopening of Wormwood Scrubs in 1942 and the resumption early in 1943 of its psychological and surgical work. Dr J C Mackwood was appointed part-time psychotherapist and Dr H K Snell was transferred from Liverpool to assist Dr H T P Young, the senior medical officer, in selecting cases for treatment. Suitable cases have been freely transferred from other establishments.

Investigation and Treatment

Before the war emphasis was laid on the investigation of suitable cases since the reopening it has been laid on treatment. Dr Young states that since 1934 much information has been collected on the type of case likely to be cured by psychotherapy in prison, and on the alternative possibility of bringing about a practical modification of the abnormal psychological processes. Prisoners deemed suitable and complying with the necessary conditions are referred to a psychotherapist for investigation if they have a general desire to undergo it. The numbers are still very small. In 1943, out of 70 male prisoners referred for investigation, only 18 were given full courses of treatment, the others being considered unsuitable either before or after investigation. The results varied from partial to complete relief. This number clearly does not represent the true proportion of prisoners who should be treated individually and, where possible, arrangements are made for some short sentence offenders to attend at a clinic after release. Here again the numbers are not large. Many prisoners prefer to forget their criminal history or will not give up the necessary time, also in certain areas facilities for treatment are limited. Nevertheless with the expected development of the mental health services the number of ex-prisoners receiving treatment should be much increased. Sending prisoners from the prison to public clinics during sentence has not been found satisfactory and is impracticable in cases requiring deep analysis, which may involve attendance every day for about two years.

In some cases anxiety is caused by the fact that the treatment specifically ordered by the court is not pursued because the prisoner is unsuitable. Other prisoners are apt to seize on the court's authoritative direction that they should have treatment as an intimation that they are regarded as not fully responsible for their crimes. For successful psychotherapy in prison one of the essentials is a desire for relief expressed before the crime was

¹ Report of the Commissioners of Prisons and Directors of Convict Prisons for the years 1942-4. H M Stationery Office Cmd 7010 1946 Pp 154 2s 6d

detected. In its absence the prisoner may be merely passively seeking the support of treatment and gratifying his anxiety for self-justification. The psychotherapist is then in the dilemma that if he gives treatment the prisoner will probably use the fact in a similar difficulty later to explain his criminal conduct, if on the other hand it is withheld, the prisoner's resentment may cancel any reformatory or stabilizing influence which the sentence might have had. The selection of cases therefore calls for great care. Moreover, the attempted treatment of unsuitable cases is bound to discredit psychotherapy as a preventive of crime. Again, if the prisoner discovers that the length of the sentence has been adjusted to the time estimated to carry out the treatment he will cease to co-operate. The speed of recovery of a case cannot be gauged before treatment has been started. Dr Young considers that as the scope and limitations of psychotherapy become more generally appreciated, the number of persons suitable for treatment during sentence will substantially increase.

Physical Methods in Psychiatric Treatment

Arrangements were made to transfer to hospital patients suitable for various forms of physical treatment. Two prisoners received insulin shock therapy and one malarial treatment. Through contact with outside authorities, cases of psychosis are thoroughly investigated with a view to physical treatment. Considerable use has been made of electro-encephalography with the help of the Sutton E.M.S. hospital. The tracings are useful in the diagnosis of obscure cases of epilepsy, and may prove valuable in ascertaining psychopathic personality, particularly of the aggressive type.

Dr G. Durrant has been appointed to Holloway as psychiatrist for women. She has examined and reported on many cases and treated suitable patients. A report on her work is promised. Arrangements have been made in prisons for both sexes to extend psychological treatment, and authority has been granted for the appointment of a psychiatric social worker at Holloway and a non-medical psychologist at Wormwood Scrubs. It is hoped that these officers will assist in the psychiatric assessment of prisoners committed to Borstal or to prison, and so enable the Commissioners to provide training according to their needs at Borstal institutions and at special centres, both existing and projected. All prisoners who appear to present some mental abnormality are examined and assessed and favourable cases with sufficiently long sentences are treated. The psychological treatment of prisoners in prison has disadvantages, and Dr Methven looks forward to the great help which will be given by the special institution recommended by Dr Norwood East and Dr de B. Hubert in their report of 1939, when it is provided.

Among recidivist prisoners transferred from Parkhurst to Dartmoor in 1932 were a number of psychopaths. It was decided to see if these men could be made to "float" instead of being nursed along in and out of the hospital. The medical officer explained to them that if they did not behave they would not be immune from disciplinary procedure. His warning worked quite well and the prisoners seemed much happier. Psychopathic behaviour disappeared, and the hospital population was lower than ever before. Firmness and understanding of the difficulties of these men helped them to carry on normally.

Prison Diet

The Ministry of Food helped the Commissioners in the autumn of 1944 to study prison diets. Dr Magnus Pyke studied the diet provided at several representative prisons and Borstals. He reported that, broadly speaking, the diet was not unsatisfactory, the only consistent weakness being some lack of vitamin C. Vitamin A was occasionally deficient and a shortage of fat rendered all the diets bulky. Borstal boys had less vitamin A in proportion to their requirements than the adult prisoners. He suggested that the right to unlimited bread should be restored (this was before bread rationing), and that at least 10 oz (283 g) of carrots be issued to prisoners and 14 oz (395 g) to Borstal inmates every week. He also advised that Borstal inmates should have eggs and more milk. The committee of medical officers which considered his report recommended a substantial increase in the bread issue and the provision of 10 oz (283 g) of carrots a week, also the increase

of the milk ration in local prisons and Borstal institutions to the maximum available in wartime. Dried eggs would, they said, be issued to hospital patients. To deal with the fat deficiency, the committee recommended the issue of 4 oz (112 g) of sausage-meat weekly. Dr Pyke's method of cooking green vegetables to save vitamin C was circulated to all establishments. After seeing the recommendations of the committee, Dr Pyke said they satisfied his criticisms.

PRINCIPLES GOVERNING NERVOUS ACTIVITY

HUGHLINGS JACKSON LECTURE BY PROF. ADRIAN

In the Section of Neurology of the Royal Society of Medicine on Jan. 2 Prof. E. D. ADRIAN, O.M., F.R.S., delivered the tenth Hughlings Jackson Lecture. The first lecture was delivered by Hughlings Jackson himself exactly fifty years ago.

Prof. Adrian began with a reference to Herbert Spencer, a philosopher who was too dry forgotten, but who had moulded the thought of his mid-Victorian generation, and whose influence was shown in the development of neurology through his great admirer Hughlings Jackson. The theories and predictions of Hughlings Jackson were based on Spencer, and the illumination which these gave to neurology was as brilliant to-day as ever. Hughlings Jackson was one of the great clinicians of all time, a scientific observer of the first rank, and his theses were still fresh and individual and none the worse for our advancing knowledge. His ideas were cast in terms so general that they applied whatever the detailed structure of the nervous system might prove to be. Many of his writings were published before the neurone theory had been properly formulated. Most of the data of clinical neurology were available then as now, but he had not got our great mass of detailed information about cell structure and cell physiology. We had no Spencer now to give us an accommodating framework, and no Hughlings Jackson to fill in the picture, but we ought to survey our own knowledge from time to time in the light of Hughlings Jackson's theories.

Evolution of the Nervous System

Hughlings Jackson described the evolution of the nervous system as proceeding from the lowest well organized centres to the highest least organized, from the most simple to the most complex, from the most automatic to the most voluntary. The stretch reflex could be instanced as an example of a low level of nervous complexity and the highest degree of organization. A higher level of complexity was shown in the flexion reflex in response to pain in which the synaptic delay was twice as long as that in the stretch reflex. The motor discharge was no longer rigidly confined to one pathway. The painful stimulus had to be avoided if the body was to escape damage, and if the danger signals persisted and increased the avoiding movements had to be more powerful, involving more and more muscles. In the flexion reflex the power of evoking intense and widespread activity was much more important than the precise localization, and this seemed to arise from the less definitely organized arrangement by which the afferent discharge had access to a whole network of internuncial neurones. The multi-neurone arrangement gave the flexion reflex its characteristic inertia and momentum, so that the motor activity increased progressively and continued as an after-discharge. In this reflex an afferent stimulus lasting one second might give a discharge ten times as long, and at higher levels the evidence of long lasting central effects became more and more striking, culminating in the cerebrum, where the results of an afferent message might be stored indefinitely to influence behaviour for many years to come. Thus there were two manifestations of central activity to explain in the lower levels the momentum, the slow rise and the long after-discharge, and in the higher levels the tendency to continue oscillations of cell activity, rhythmic pulsations modified by but not obviously dependent on the afferent signals. The evidence for the pulsations depended on electrical changes rather than on motor effects, but it was clearly a constant feature in cerebral organization.

One hypothesis put forward recently in neuro-physiology related both the momentum and the rhythm to a single cause, namely the widespread connexions formed by the dendrites with internuncial neurones. In this view protracted discharges from the spinal cord were supposed to be due to a continued bombardment of the motor neurones by impulses reaching them by multiple pathways. The idea was attractive at first sight because it could be made to explain so many features of neurological activity, but there was no convincing proof of the reverberating circles in the higher nervous levels, and there was convincing evidence of quite another kind of activity, namely, electrical effects which occurred with an afferent "volley".

The Electrical Hypothesis

The spread of excitation through a mass of nerve cells was guided to some extent by the pathways formed by the dendrites, but it was possible that outside the well organized pathways more diffuse connexions at high levels might depend to some extent on the electrical fields generated by the active areas. This was a different conception from that of the school which thought chiefly in terms of *dendrite connexion and reverberating pathways*. The idea of the association of neurones by electrical rather than by direct neural influence was not new, but some fresh evidence for it had recently appeared. It had been shown that the two halves of a frog's heart, completely separated by a cut and then brought into contact, might influence one another enough to make them beat synchronously. There were many points to be learned about this mode of interaction which was diffuse, covering wide fields and varying with intensity and distance. Continued rhythmic activity was characteristic of the higher centres. In the cerebral cortex a continued oscillation of electrical potential was found, it was uniform over considerable areas and whatever its cause it meant that neurones could not be thought of as being in the same state from one moment to another. If they were not all synchronous an afferent signal would find some neurones refractory and some excitable. The tendency to rhythmical activity in the neurones of the higher centres and the possibility of influence by electrical rather than by dendritic connexions were two factors which had to be considered in forming an idea of the organization of the cerebral cortex.

Uniform low-frequency levels seemed to be established in the cortex when the disturbing influence of afferent signals was excluded. When afferent signals arrived their rhythm was taken up and the cortex entered on the irregular heterogeneous activity which was presumably necessary for ordinary discriminating behaviour, but if the excitation was intense or the cells were highly active a rapid uniform rhythm might spread. In the cerebrum an exciting agent (or an injury) might set up a uniform rhythmic activity with a period of about 60 a second, in the cerebellum a rather different plan seemed to be followed, with a rhythm of higher frequency (150 to 250 a second). This was maintained by the constant inflow of afferent signals. If an additional message was sent in the waves increased in size and regularity most of all at the point of arrival of the message, though to some extent in all limb areas on that side.

High-frequency synchronization could be achieved by electrical spread from one neurone to another. It could occur at the cut end of a nerve trunk and it was favoured by abnormal conditions likely to modify the membrane of the cell. It occurred only over the higher frequency ranges, with minor degrees of excitation the neurones responded at widely different frequencies. As they approached their maximum rate of discharge one group of neurones would act as pacemaker, and then a large number of elements beating in unison would produce an alternating field great enough to cause units not so strongly organized to resonate. This effect could certainly obtain in the normal behaviour of large cell masses and might dominate their behaviour in abnormal states.

Cell Activity at the Higher Levels

In speculating on activity in diffuse electrical fields there was some danger of forgetting to think in terms of *fixed anatomical connexions*. In the cerebrum heterogeneous localized discriminatory activity was essential and depended to a great extent on structural differences, but it seemed to depend also

on factors unrelated to structure, particularly on the great instability of the cells at the higher levels. Little idea could be formed of the patterns in the higher centres, in which the neural equivalent of what went on in the mind, its powers of memory and problem solving, must be sought. What kind of patterns of cell activity might be expected at the higher levels? The activity seemed to depend less on neural connexions than on the general balance of excitation. On both the sensory and the motor side the central patterns seemed to have no precise localization, no necessary connexion with particular neurones. There were such facilities as the recognition of the face of a known person in a photograph notwithstanding the complete change of scale, or the way in which a skilled act could be done by the left hand when the trained right hand was injured. The spreading electrical fields producing synchronous activity might account for some of these things, though there remained a great deal still to be explained.

Some clue to the nature of the pattern might be obtained by bearing in mind that purposive acts must be moulded by the afferent nervous patterns. These continued as a spur to action until the aim, whatever it might be (turning the gaze or closing the hand), was achieved. When that achievement was signalled along the afferent pathways the disturbance subsided. The broad afferent pattern—the temporary and spatial distribution of sensory activity which signalized the accomplishment of the aim—seemed to be uniquely related to the disturbance. This was, in a way, the inverse of the existing pattern—the key which fitted the particular lock. That seemed to be a hypothesis on which it was worth while to work in endeavouring to elicit the exact neural mechanism in the higher centres. Such a scheme must obviously account for the most complex as well as the most simple activities—the planning of one's career as well as the putting of one foot before the other. The drawback in all such speculation was that if one thought too far along one line one was likely to become so enamoured of the prospect as to be unwilling to risk experiments which might show it to be an illusion, nevertheless it was a possible line of investigation, and that was its justification.

MEDICAL SOCIETY OF THE LCC SERVICE

The annual general meeting was held at County Hall on Jan 6 1947. Sir Allen Daley, the retiring president, was made honorary president, and Dr R C Harkness was elected president. Mr J R M Whigham, of St Andrew's Hospital, was appointed chairman for the ensuing year.

Mr G F STEBBING, the retiring chairman, gave an address on the "Organization of Cancer Treatment". The broad principles which must be common to all organizations for the treatment of cancer were outlined. The general practitioner must be persuaded to keep cancer constantly in front of his mind, and he must be encouraged to send even slight ailments for investigation by specialist teams. These teams must work under the best conditions and there must not be too many of them. Some surgeons would have to give up the idea of treating cancer of any kind, and all surgeons would have to agree to concentrate their attention so far as cancer was concerned on certain sites allotted to them by the cancer organization. The follow-up of cancer patients must be jointly arranged by all the specialists concerned and by the general practitioner, who should be kept fully informed at every stage of the treatment. All cases should be followed up to their conclusion, especially those in which treatment failed or had not been attempted. The knowledge obtained from necropsies should always be fully correlated with any treatment that had been given.

"How long do you sleep?" Questions relating to this problem were recently put by the Gallup Poll to a sample section of the population and the results reported in the *News Chronicle* on Jan 30. It was found that 50-60% of men and women went to bed between 10 p.m. and midnight and rose between 6 and 7.30 a.m. About 20-25% went to bed before that time and between 20 and 30% rose after 7.45 a.m. Most men and women sleep 7 to 8 hours a night. It was found that unoccupied unemployed and retired people had the highest average length of sleep—about 9 hours—with as many as 31% sleeping 10 hours.

Correspondence

The Pemmican B M J

SIR—Notwithstanding that I have no mandate from my 50 000 odd fellow members I feel sure that I express their feelings as I certainly do my own, when I write to congratulate you and your surprising new printer on the production of No 4494 of the *British Medical Journal*

Just as in the disastrous days of war so now in the even more drastic ones of the peace that passeth understanding a motiveless malignity' endeavours to make you cease from uttering your weekly words of wisdom

Doubtless Galileo had the *B M J* in mind when he murmured 'Eppur si muove' In other words, 'Publish yourselves to the sky'

To you, Sir, and all concerned, our congratulations and thanks—I am, etc.,

Bristol

RICHARD J A BERRY

SIR—Very warm congratulations on the production of the current issue of the *B M J* I hope that our great Association will defy all Ministers and their regulations and continue to publish these attenuated editions until the ordinary issues can be resumed

It reminds me of the things published in the General Strike (1926) of which I have a collection

Good luck—I am, etc.,

Taplow Bucks

G GREY TURNER

SIR—I wish to take this opportunity to congratulate you on producing the *Journal* in its present spectral form, which is so vastly better than no *Journal* at all Few if any periodicals would have the novel conception or the drive to release an issue in similar tabloid edition, and one could wish that the authorities in power at the moment had as much conation It savours of British tradition more than anything Parliamentary to date One is reminded of the exhortation to Naval personnel during the war 'The difficult we can do at once, the impossible takes a little longer'—I am, etc

Warrington

P A M ROBERTSON

SIR—Congratulations on the candle-light edition of the *B M J* and thanks to the Secretary 'printer' Excellent tabloid and sustains the unbroken record of the *Journal* Am sure the whole profession is grateful and appreciative Thanks—I am, etc.,

London W 1

A BROMAN

SIR—My congratulations on your enterprise As a symbol quite apart from its contents I think this week's edition of the *B M J* has tremendous significance Would that the Government would show evidence of similar enterprise—I am, etc.,

Oxford

JOHN STALLWORTHY

SIR—One million congratulations on this week's potted *B M J* and especially on its touches of dry humour—I am, etc.,

Taplow Bucks

E GREY TURNER

SIR—Please allow me to congratulate you on *B M J* of Feb 22 it is a magnificent effort and seems to have more in it than some of the earlier journals—I am, etc.,

Dumfries

A P BERTWISTLE

SIR—It was with great satisfaction and real pleasure that I received the *British Medical Journal* of Feb 22 The way in which the salient features were condensed without losing the characteristic form of the *Journal* betokens positive inspiration on the part of the creator I feel that in all the circumstances the issue was a triumph—I am, etc.,

Sennybridge Brecon S Wales

N E MELLING

* We have received many other letters and messages of appreciation of our two Pemmican issues—Ed *B M J*

Dietetic Factors in Liver Disease

SIR—Every medical student knows or ought to know, that patients with acute necrosis of the liver may succumb before the development of jaundice, and Dr P H Wilcox (Feb 15 p 266) should have realized that what I was describing (Jan 11, p 45) was not the unusual case of acute necrosis but the type of case which would carry conviction in therapeutic trials I should, therefore, have ignored his letter if it had not been for his aggressive defence of the use of the term 'toxic jaundice' in a sense which has confused a generation of medical students Toxic means produced by a poison or chemical as in toxic encephalitis, toxic myocarditis and toxic nephritis To call a lesion produced by a virus or micro organism toxic is an inaccurate use of the English language and of medical terminology If jaundice is to be classified on the lines which Dr Wilcox suggests, then the correct terms are haemolytic hepato-cellular and obstructive This familiar classification is of limited value and is liable to degenerate into a pseudo-scientific application of the van den Bergh reaction Analysis reveals that it is essentially topographic in significance and refers to the place where the jaundice originates rather than the aetiological factor which produces it The difficulty in using such a classification is illustrated by the fact that haemolytic jaundice is often toxic in origin—i.e., produced by a biological toxin or a chemical poison—and it always has a hepato-cellular component which may be in part obstruction For this reason it would be better to use the terms pre-hepatic hepatic and post-hepatic jaundice on analogy with uraemia—I am, etc.,

Oxford

L J WITTS

Treatment of Pernicious Anaemia

SIR—Through the courtesy of Messrs Lederle Laboratories Inc we have been supplied with sufficient folic acid to treat some 40 patients during the past eighteen months These patients were suffering from a variety of diseases and eleven cases of pernicious anaemia were included Three of these patients suffered from subacute combined degeneration of the cord In two of the cases no objective or subjective improvement resulted from therapy with synthetic L casei factor while in the third case the neurological changes progressed rapidly during treatment even when the dose of folic acid was raised to 20 mg daily by mouth Marked improvement resulted from intensive parenteral treatment with anahæmin We reported these observations to Messrs Lederle because of the serious implications which obviously accrued therefrom Accordingly we were not (*Lancet*, 1947 1, 174) surprised to read the clear evidence presented by Spies and Stone that synthetic folic acid and synthetic thymine will neither prevent the development of subacute combined degeneration of the cord in Addisonian pernicious anaemia nor relieve it once it has developed

These findings indicate that folic acid should not be used as the sole therapeutic agent in pernicious anaemia except possibly as a temporary measure Until the specific factor for the maintenance of the integrity of the central nervous system has been discovered parenteral liver therapy must continue to be the accepted method of treatment both for pernicious anaemia and its neurological complications It may be shown in the future however that a combination of folic acid and liver therapy is more satisfactory than either method individually

In parenthesis we would mention that we have confirmed Spies' claim with regard to the haemopoietic effects of synthetic thymine in Addisonian pernicious anaemia The material was supplied by courtesy of Messrs Genatosan Ltd—We are, etc.,

STANLEY DAVIDSON
R H GIRDWOOD

Edinburgh

National Health Service

SIR,—The beginnings of the National Health Service are being forgotten by the lay public and the medical profession alike Let me recapitulate A Beveridge plan was produced by a Liberal taken up by the Conservatives, and actuated by the Socialists Social security was the advance, and no party could allow this luscious plum to fall outside its vote-catching ambit Here was something that far transcended nomenclature for fourpence The employee must now pay 4s 7

week, and the employer pays a contribution as well, and the end result must be about ten times as good—or is it? But to make social insurance work it had to be implemented by a National Health Service. It was not that the present health service of this country was so bad that it needed reformation, but that a social insurance scheme could not work financially without control of certification. It was Mr Ernest Brown when Minister of Health, who let the cat out of the bag when he stated that social insurance required control of the doctors in order to control certification. Having made that statement he was shortly out of office. Facts like that must not be put so bluntly.

If the country—not the politicians—had said the medical service of this country was bad and reformation necessary, I would be the first to help plan something better, but it is a fact that medical practice in this country (and I speak particularly of the general practitioner service) is much better and fairer than in any other country. Speaking of the countries before the last war, compare it with general practice in the provinces of France, Germany, U.S.A., Austria, Denmark to name only a few of the more advanced countries in a medical sense. Paris, Berlin, Vienna, etc., were first class, but outside these capitals and outside the specialist classes the general practitioner was in no way comparable to our own. I think this is universally admitted.

Do not for a moment think that I am suggesting a smug complacency in this respect, there is never a good but it could be better. Medical practice here could be vastly improved, not by turning it upside down and nationalizing it, but by a system of grants and without the expenditure of £66 000 000. How we have always longed for a pathological service easily available and *at our doorstep* a consultant *at the bedside* to name but two advances, and all this could be done with a few strokes of the Minister's pen and a relatively small grant. But no the Government's argument is this, though not stated. We never said your present service is bad. We are not concerned with the welfare of the patient. But within a social security scheme patients, doctors and their certifications must be controlled to enable the organization to work in a Civil-Service like manner. At the same time we as a Government must make it look as if it was a forward step in medicine so we advertise it as free medical treatment for all—all hospitals and consultants available to the richest and the poorest. That is the Government's propaganda.

The best hospitals and best consultants were always available to the poor and sick. Change is not always for the better. The general practitioners and the specialists cannot be changed overnight by a degrading change to Civil Service. If I thought that the Government had at heart a real desire to help medicine I would be the first to join a new service, but I am afraid their intentions are purely political and merely to implement social security. Let us keep the origins and intentions of this scheme ever before us, and we shall see its falsity. By not negotiating we can never be accused of being part and parcel of it. Let us keep our hands clean and reserve our decision to the final plebiscite.

—I am, etc.,

High Wycombe Bucks

W J O'CONNOR

SIR,—Among the interesting correspondence in your columns on the subject of the National Health Act I am surprised to find that among the many objections raised there has not been more opposition on the grounds of the inexpediency of attempting to work such an Act at a time when the public is suffering from poor and monotonous diet, housing shortages, and the very serious shortage of nurses and beds in hospitals. It would seem to be a matter of simple common sense for the Government to deal first with these shortages. Action on these lines would do more to improve general health than the creation of an expensive service involving still more official forms and countless office boys.

Apart from the unwise timing of this new Act, which, from questioning many patients, I am convinced is by no means popular, and the fact that the financial state of the country hardly permits one to believe that it can be implemented in 1948 there is a very serious drawback from the general practitioner's point of view, and this drawback is seldom mentioned. This is that the surgery hours will be swamped by elderly chronic cases leaving too little time for attendance on workers and young people. This is already apt to happen when the doctor is a district M.O. Much illness and distress among the elderly is due, not to lack of medical care, but to lack of suitable

accommodation and simple domestic help. But it is obviously easier for Mr Bevan to create more forms than more houses for the people. Doctors' surgeries are already overcrowded with chronic cases for whom little can be done medically, to the detriment of workers who do not want to spend weary hours in waiting rooms.

I would like to add one more point. Some doctors, by no means all of one political persuasion, find the prospect of the new Act attractive because they envisage working for limited hours, perhaps in a kind of rota, and in well equipped clinics. There would be much to be said for this, but there is no guarantee whatsoever that the doctor will have even a twelve hour day. The quasi humanitarian attitude of 'You couldn't do that' towards doctors may be very meanly used to press them to accept all the drawbacks of Civil Service without its concomitant advantages in the form of set hours. As for the building of new clinics, it is possible that they may appear in time—probably a long time—but meanwhile most general practitioners will still have to use their own homes for professional purposes and their wives will still be slaves to the telephone—a situation unknown in other branches of the Civil Service and if the present Government has its way the bulk of the profession will be members of a kind—a very over-driven, onerous kind—of Civil Service. The trap is widely open for all who have eyes to see—I am, etc.,

London W 4

JOHN C C LANGFORD

SIR,—I am disturbed to find considerable evidence of differences of opinion within the profession as to what constitutes the principal objection to the National Health Service Act and Mr Bevan's relevant proposals. An attempt to sum up the position may not be amiss. The possible bones of contention would seem to be principally (1) The tribunal, (2) abolition of purchase and sale, (3) so called 'direction', (4) payment by salary. In my submission the essential objection on which a stand must be made is the salary. I believe that all the other objectionable features are offshoots of that idea.

All attempts from within the profession to obtain a Government organized comprehensive health service for the nation failed. It has only been when the necessity for controlled certification has arisen (*vide* Lord Beveridge, the present Lord Chancellor, *et al*) that governments have sponsored plans for a service. That is to say, historically the origin of the proposed Service is based on the Treasury's urgent desire to control the doctors. The obvious way to control them is to employ them, and the way to employ them is to pay them a salary—whole or so called basic. If we fail to keep this fact before us and to recognize the salary as not only the main theme but as the very *raison d'être* of the whole scheme we are in grave danger of losing all.

The tribunal is a red herring brought into the limelight in the dubious presidential ministerial correspondence. It is possible that the Ministry intends 'concessions' here as bait, knowing full well that such concessions would be of little or even no value. It will be the most natural thing for a contract between an employer and an employee to carry a clause making it terminable by so many months' notice on either side (the alternative is a contract to be binding for ever, and this seems fantastic). If such a clause is ever invoked no reasons would have to be given, and no tribunal or law court could be interested. The only true safeguard is to refuse to have a single overriding employer—i.e., to refuse any form of salary. Then the right of appeal to a court will have real value.

Abolition of purchase and sale is not in my view, political or associated with any policy of nationalization. Some see it as a pistol held at our heads, but though it has this effect I do not think that it is based on such an intention. An offer of compensation must have a time limit set to it—the Government cannot offer to buy medical practices *ad lib* for ever. Whether the time limit is the 'appointed day' or *x* months after that day is of small moment, while the former is the obvious logical choice. The Minister pretends that the abolition of purchase and sale has some high moral virtue. The simple fact is that purchase and sale cannot persist in a salaried service. Accept a salary and we have no possibility of retaining the right to buy and sell but reject a salary and the Minister is left with no valid reason for depriving us of the right.

Dr K M M Sheldon (Feb 1, p 195) attributes to 'capitation fee' the faults which result from 'inadequate capitation fee'. Let us make sure in all our discussions on the new service that 'capitation fee' is synonymous with 'adequate capitation fee'—adequate to prevent the wrongs which Dr Sheldon so rightly condemns.

So called "direction" is similarly an outgrowth of the salary idea. The Minister pretends that the aim is a better distribution of doctors, but this is obvious eyewash. The simple fact again is that it is an essential part of a salaried service. A salaried school teacher, salaried dustman, or salaried M.O.H. cannot earn his living as such except where a vacancy in a service occurs. The same would be true of salaried general practitioners. The Minister's real reasons for this objectionable feature, too, therefore evaporate when the salary idea is removed.

Let us then keep the salary idea in the forefront of the picture. Let us if he is persistent, fight the Minister on this issue, which if won can win all, but which if lost *must* lose all—I am, etc.,

West Bromwich Staffs

D. SAKLATVALA

SIR—Among many possible disadvantages to general practitioners working under the new Health Service scheme there is one attraction which will surely count for much. It is likely that simple pathological investigations and routine radiographs with expert interpretations will be available to patients without the necessity of first consulting a specialist.

In many places in this country the fantastic situation exists whereby a general practitioner who wishes to have his patient's blood count estimated or his chest x-rayed must first obtain the approval of a consultant. Under such a system the patient is often unnecessarily inconvenienced by having to wait in an already overcrowded out-patient department, the specialist is given unnecessary work, and the general practitioner is denied the right of direct control of his patient's case, as in the event of his suspicions being justified and an abnormality being found in the blood or the chest film, he is often not considered capable of dealing with it. In such circumstances is it surprising that a diminishing number of newly qualified men are looking to general practice to give them satisfaction for their abilities?—I am, etc.,

Southampton

J. L. LEWIS

The So-called Health Service

SIR—Surely we can agree that private practice must be defended from wilful destruction. There will be a great many patients and doctors who prefer it to State medicine. The two forms of service could run side by side, but Mr. Bevan intends that there shall be no alternative to his plan. It obscures the facts to say that under his Act doctors need not join the Service and are free to practise outside it if they so choose. All hospitals are to be seized, and no doctor outside the Service is to have access to them for treating his or her patients, and the Act empowers the Minister to deal likewise with nursing homes if he deems it desirable—which means of course that they *will* be seized if it is found that they enable private practice to be carried on. In short it is to be made impossible for a doctor to earn a living except as a Government employee. He is not forbidden to, oh no, he will just be prevented.

Certain writers in this *Journal* and elsewhere seem to think that it is our moral duty to become salaried State officials because that represents the will of the people. To me that appears wide of the mark. The masses have no more idea of the consequences than a child who wants to bathe in a whirlpool. The medical profession holds a key position as one of the guardians of personal freedom—our own included, though some have foolishly suggested that we ought not to pay any consideration to this latter—and I submit that even those who wish to work in a State medical service should decline to join until the provisions for State monopoly and dictatorship embodied in the present Act are abolished—I am, etc.,

D. PRIESTLEY SMITH

Penicillin Lozenges

SIR—Some investigations are being made at the Dental Department of this hospital concerning the effects of penicillin lozenges and other preparations used locally in the mouth. Correspondence in the *BMJ* in recent months indicates interest in the subject and it would be much appreciated if those who have had cases of discoloured and sore tongue following the use of penicillin orally would kindly communicate with the writer of this letter giving details—I am, etc.,

Dental Department

Guy's Hospital, London Bridge S.E.1

W. G. CROSS

Penicillin Treatment of Carbuncles

SIR—The dosage of penicillin in the treatment of carbuncles described in "Any Questions?" (Feb 1, p. 207) is cumbersome and administered only with considerable inconvenience to the patient. In a busy casualty department I have found that even very serious carbuncles are cured by twice daily injections of 200,000 units given intramuscularly for five days.

A typical case is that of a man aged 33 with a large carbuncle of the upper lip with early sinuses inside the nose and at the muco-odontal junction. He had had the condition for five days before coming to hospital. Insistent requests to incise the carbuncle were firmly refused, and the patient was assured of considerable relief in one or two days and virtual cure within five days. He was then started on a course of 200,000 units twice daily for five days. After 24 hours the patient felt much better, and sloughs were removed on the third and fourth days. In view of the dangerous site of the carbuncle infra-red was given as an additional precaution, and continued for three days after the full course of penicillin. By the eighth day no further treatment was necessary. All the while the patient was ambulant, and he attended Casualty for his injections.

For surface carbuncles local hot applications are used, and only dry dressings are necessary at the end of five days. Infra-red is not used as a routine. There have been no metastatic complications whatever with this treatment. I have found that penicillin in oil does not give the same dramatic results even when high dosage—250,000 b.d. for four days—has been used. The advantages of the high-dosage penicillin therapy described lie in its dramatic success without surgical interference and in its simplicity; the patient is ambulant throughout treatment, which can therefore be carried out in the consulting-room or in a casualty department. There is the minimum of dislocation of the patient's life and more hospital beds are freed for other purposes—a not inconsiderable factor at the present time—I am, etc.,

Mitcham Surrey

S. GOLDWATER

Reiter's Disease

SIR—The triad of symptoms grouped together as "Reiter's syndrome"—viz, purulent conjunctivitis, polyarthritis and urethral discharge—as described in the *BMJ* Aug 10 1946 (p. 197) is sufficiently unusual to make diagnosis of the condition easy. Such a case treated in this hospital recently illustrates the condition, and in view of its apparent rarity seems worth recording.

CASE REPORT

A battery sergeant major aged 25 developed a scanty mucoid urethral discharge on a troopship returning to India from U.K. on Aug. 22 1946. There was a history of exposure on the 9th he was assumed on dubious grounds to be suffering from gonorrhoea and given a course of penicillin (total 150,000 units) without benefit. The discharge continuing he was admitted to C.M.H. Secunderabad, on Sept. 3. Repeated smears failed to show any gonococci, though there were extracellular Gram positive organisms. On Sept. 8 he developed a subacute arthritis of the mid-tarsal joints of the right foot with reddening of overlying skin and the right eye showed intense conjunctivitis with chemosis and mucopurulent discharge. The urethral discharge at this time was so severe that there were numerous mental erosions. The eye was treated locally with mercuriochrome and saline irrigations and he was given a sulphathiazole course for 5 days (30 g). This improved the urethral discharge but not the other symptoms and on Sept. 10 he was complaining of stiffness of the left temporomandibular joint and pain in the left tarsal joints as well.

By Sept. 17 the conjunctivitis had settled and the urethral discharge was much less, but he was running a remittent pyrexia of 99–100° F (37.2–37.8° C) and sedimentation rate was 100 mm first hour. Both the mid-tarsal joints now showed signs of inflammation and the left knee was somewhat swollen. A second course of penicillin (30,000 units 3 hourly for 30 injections total 0.9 mega-units) had no effect on either the pyrexia or the arthritis and on Sept. 27 the left mandibular, both mid-tarsal and left knee-joints were still unchanged. In October he developed a huge effusion in the left knee, and 50 ml of greenish fluid were withdrawn on the 15th, this was sterile on culture. During late October there was a recurrence of urethral discharge, which was again improved by a short course of sulphathiazole. The pyrexia settled by mid-November. On Oct. 30 B.S.R. was 50 mm/hour on Nov. 25 22 mm/hour, and by Dec. 7 it had fallen to 7 mm/hour only. The arthritis of knees and tarsal regions slowly subsided the later stages

helped by quadriceps exercises and radiant heat. Subsequent convalescence though slow, was uneventful. Negative investigations included stool examinations, culture of urine and 24 hour specimen for the acid fast bacillus, x rays of the affected joints and also of the chest. Leucocyte counts in the acute stage varied between six and nine thousand cells per cmm (P 70% L 25%, M 3% E 2%). Blood culture was sterile.

The patient illustrates the salient features of the disease including the liability to sudden serous joint effusions and the subacute but self-limited course. The duration of nearly four months coincides pretty well with the cases written up by Jackson and by Wrigley (*ibid*, p 199). He also appears to have been helped by sulphathiazole as were their cases.

It is one of the many annoying features about medicine in India that many special investigations are not available, including the gonococcal complement fixation test but there was no clinical doubt that this was not a case of gonococcal arthritis but of the rarer Reiter's syndrome—I am, etc,

K W G HEATHFIELD,
Capt R A M C

Secunderabad India

SIR—The article by Flight-Lieut W P U Jackson (Aug 10, 1946, p 197) and comments on same by Drs R N Herson and Frank Marsh (Aug 24 p 275) and by Dr Joseph Denfield (Oct 12 p 555) have moved us to write this letter. In 1943 in our article on virus infection of genitalia (*Rev chil Hig*, 5, 253) we referred to the existence of a positive Frei test, eye fundus oedema and of deep iliac lymph node inflammation in typical and *frustes* forms of so-called Reiter's disease and attributed the syndrome complex to the action of lymphogranuloma venereum virus. In some cases the disease was accompanied by an abacterial urethritis, but in most the discharge contained gonococci. L V-gonorrhea association is not infrequent, as pointed out by us in 1943 (*Brit J vener Dis* 19 37).

A similar condition to that observed in males was described by us in women in 1944 (*Obstet Gynec Lat amer* 2 9). The existence of a positive Frei test, typical L V eye fundus findings, and other evidence of L V infection were also found by us in so called Behcet's syndrome and also published in aforementioned articles. If colleagues have interest in reading articles published in Spanish, reprints will be gladly forwarded on request—I am, etc,

W E COURTS

Cerebral Malaria in Great Britain

SIR—Both in Britain and in tropical climates malarial infection is frequently associated with intercurrent infections. Parasites may be found in blood films and the prognosis altered accordingly. Acute bronchitis, pneumonia, and typhus fever (10% of my 493 cases), and cerebrospinal fever were perhaps the most noteworthy associated infections in my experience in the Far East (1942-6). I had three cases of meningococcal meningitis associated with malaria (positive blood films). Treatment was directed to the meningitis first, and the malarial infection was concurrently treated with quinine and mepacrine.

It therefore caused me some surprise to read that Dr Walter Broadbent (Jan 4 p 32) was so ready to diagnose cerebral malaria in the case of a man with fever and meningism who had recently returned from West Africa, even assuming that he found malarial parasites in blood films. In my experience meningism was not always found in cerebral malaria, and in such a case as he describes I could not have rested content without first examining the cerebrospinal fluid to exclude meningitis. Although in this particular case his diagnosis was correct and was to be commended I submit that the assumption that every case of fever associated with meningism and positive blood film is one of malaria only may lead to disaster, because meningitis, which may sometimes be present in addition, may escape recognition and treatment. Likewise pneumonia may often escape recognition where malaria cases are diagnosed by blood films. Indeed it was my custom in my division of the military hospital in which I was stationed to be on the look-out for chest signs among the many malarial cases under treatment. It was not an infrequent occurrence to recognize pneumonic signs in cases previously missed by medical officers.

I think these points should be mentioned in view of the fact that malarial relapses may at any time arise among certain persons returned from overseas, and may come under the care of practitioners inexperienced in (and sometimes ignorant of) the disease and its associations. Relapses of malaria are common in the cold weather, but fresh cases are only likely to arise in spells of hot weather. While the disease should be suspected in any person with fever recently returned from an endemic area and cases in doubt should be treated, it is of equal importance to see that superadded infections such as pneumonia and meningitis should not remain untreated in the early stage, even in those cases in which parasites are found on examination of the blood films—I am, etc,

Windsor Berks

PHILIP H WILLCOX

Early Diagnosis of Tuberculosis in Adolescents

SIR—In view of the great increase of tuberculosis among the 15-25-years group of the population and the impracticability of mass radiography as a general routine, would it not be a good thing if all 'school leavers' were tested by the tuberculin patch or inunction method? 'Negative reactors' could then be followed up by repeat tests at frequent intervals of, say, about three months.

This type of test would be simple to apply and would be less terrifying to the child (or parent) than the needle. It would also save the time of parents and children who might have to attend some clinic—perhaps at a distance from both home and school—for mass radiography. It would be a simple test quickly applied and easily checked and should help to keep under supervision all "negative reactors" when they enter industry or other spheres.

If the result of the test were entered on the school medical record card it would (or should) reach the doctor on whose panel list the young person is entered. If there is a medical officer—as there is in Aberdeen—to supervise the health of the students it could be forwarded to the university medical officer or the training centre medical officer and so complete the follow-up during those years of great susceptibility—I am, etc,

Aberdeen

WINNIEFRED M GRAY

Chemoprophylaxis of Rheumatic Disease

SIR,—It has been rightly or wrongly, attributed to the rarity of nasopharyngitis that acute and chronic rheumatic polyarthritis and rheumatic heart disease common to both tropical and temperate zones^{1,2} are unknown among nomadic Lapps.³ For fifteen years it has been noted that a nasopharyngitis (phase 1) or indeed a mild gastroenteritis precedes the efflorescence of rheumatic fever or idiopathic rheumatoid arthritis (phase 3) by a "latent phase 2 of 5-40 days".^{4,5} The chemoprophylaxis of phase 1 is based on the assumption that haemolytic streptococci (group A) are the essential organisms in their bacterial flora. In my experience this is not necessarily so.

The action of penicillin or sulphonamides is not anti-rheumatic.⁶ The latter aggravate a smouldering rheumatic infection and must be used cautiously. Even in the latent phase 2 frequent electrocardiograms disclose myocardial mischief. Further Swift,⁷ who has emphasized that in children a chronic rheumatic carditis may show persistent activity for months and even years notes that subclinical rheumatic relapses occur with a frequency hitherto unsuspected as disclosed by the careful records of body temperature, sleeping pulse (over 80 abnormal for children adult normal 60-65)¹⁴ and ancillary laboratory tests. Because abnormalities may be transient electrocardiograms are needed daily or bi-weekly. While other abnormal causes must be excluded with positive tests both the ESR and leucocyte count (examined prior to noon because of diurnal tides³ abnormal—9 000 or over)¹⁵ may be normal in the presence of active infection, in such cases the formal gel reaction is abnormal.⁷ Usually there is a close correspondence between ESR, leucocyte count, and body temperature (10 minutes orally).

An invaluable common sign hitherto undescribed of rheumatic infection is a sudden onset of mild to moderate tenderness and tenseness of finger pads, the overlying skin being dark red in colour transient in 48 hours but aggravated by trauma (watch

winding or writing) and indistinguishable from Osler's digital nodes. A similar complaint is seen in rheumatoid arthritis and in epidemic polyarthritis.⁸ Chronic rheumatic carditis may present a transient bacteraemia, splenomegaly, purpura (petechia, subungual splinter, and subconjunctival) and be confused with septic endocarditis, in 10% of which the blood culture is persistently negative.¹⁵ Both may coexist.^{10, 15} The absolute diagnostic criteria of the latter are organic heart disease plus a persistently positive blood culture (non-specific) or infective emboli. Penicillin therapy would be diagnostic if curative.

Chronic persistent rheumatic carditis in an adult has hitherto not been reported but I have witnessed such a case resulting from the too early mobilization of an acute myocarditis prior to the disappearance of the abnormalities of the ECG. For the chronic as for the acute carditis complete bed rest is essential.¹⁰ Comparison of the recent cardiac research in idiopathic rheumatoid arthritis with the usual sad course and prognosis of chronic rheumatic carditis demonstrates its validity. Of the 60-70% of the bedridden or inactive patients presenting inflammatory heart disease post mortem less than 25% was detected clinically during their illness.^{11, 12} The management of rheumatic fever is still a test of the skill of a physician—I am, etc.

Nocturnal Drip Feeding

SIR—In pulmonary tuberculosis the patient who needs food most on account of loss of weight, fever, and malnutrition is usually he who can eat least owing to loss of appetite. Rest and other measures to decrease 'toxaemia' usually check the patient's downward course by restoring appetite sufficiently to maintain a credit on the nitrogenous and calorific balance sheets but this is not always the case. Bullying or very strong persuasion to stuff results in dyspepsia and disgust for food.

Although calories are being spent night and day it is usual and convenient to take in a 24-hour supply of food during the daytime and this is of course possible except when the appetite is poor. It would seem rational therefore to use the night as well as the day for feeding, and this would be most easily done by a nocturnal drip feed (NDF) of hydrolysed protein and glucose. NDF offers the following advantages: (1) Almost empty stomach all night and so unlikely to encourage nausea and feeling of fullness, (2) would not mean waking for meals in night, (3) would give "round the clock" nutrition, so that patient would absorb almost two days' food in one day, (4) would conquer the difficulty that anorexia puts in the way of high calorie and high protein diet, (5) would not interfere with appetite for next days food.

Patients will co-operate if it is explained that they are getting the equivalent of two beef-steaks while they sleep. Hydrolysed protein is easy to obtain. A metal reservoir, a Ryle's tube, and glass drip connexion are the simple requirements. No experimental proof of effect is here offered. Those who care to try the suggested method will find that the 'proof of the pudding is in the eating'—I am, etc.

Physics in Medicine

SIR—I have read the article on the implication of physics in medicine by my learned teacher Prof F L Hopwood and his distinguished colleagues (Feb 15, p 261) with considerable interest. As a first-year student I often had heart burnings as to how much of the physics I was being taught had any direct bearing on my future status as a medical practitioner. I came to the conclusion that apart from its being a useful exercise

in mathematical deduction and scientific observation it could be usefully pruned of many of its components. I feel that the mechanics section and a good deal of that devoted to heat could be considerably reduced in amount. To compensate for these reductions the time saved could be given up to a study of the elements of atomic physics and of the groundwork of physics as it is reflected in subsequent radiodiagnosis and radiotherapeutics. In this connexion instruction for the student in the handling of the x-ray apparatus could be of some service. A practitioner with a knowledge of the operation of, e.g., a portable unit could be a useful member of any medical fraternity.

It would be useful too if special sessions were arranged in the clinical years for study of film interpretation. How few of us, I feel sure, are competent to read normal, let alone abnormal radiographs in a correct manner! How often do the reports of fellow radiodiagnosticians conflict the one with the other, especially in the elucidation of thoracic and cranial lesions with their frequent intriguing shadows!—I am, etc.

Devonport

J B GURNEY SMITH

Endocrines in Gynaecology

SIR—May I add somewhat belatedly to the comments you have already published on Mr Aleck Bourne's paper (Jan 18 p 79)? As Dr G I M Swyer (Feb 1 p 198) and Dr S L Simpson (Feb 15, p 270) have already said, there is nothing new in the concept of varying tissue sensitivity to hormones, but there was good reason for Mr Bourne to stress it, for it is often neglected in practice. One may add to the examples already given and point out that sensitivity may vary from individual to individual, which makes the expression of exact dosage difficult from one side of an individual to another (as in unilateral gynaecomastia, fibroadenosis, and acromegaly) from one part of an organ to another (as in nodular goitre and again in fibroadenosis of the breast), as well as from one whole organ to another as in the example quoted by Mr Bourne and in a patient once under my care who suffered from both atrophic rhinitis and fibroadenosis of the breasts. In this unfortunate patient I found that the fibroadenosis responded well to androgens and that the atrophic rhinitis was rapidly relieved by oestrogens, which, however, made the fibroadenosis worse. The problem was solved by local administration of testosterone ointment to the breasts and of oestradiol in oil to the nose.

There are, however, two statements in Mr Bourne's paper with which I cannot agree. He states that "primary amenorrhoea can never be cured." It is true that cures are rare but I have seen two recoveries among many failures. The more recent was a young Jewess of 17 with an infantile figure, no visible or palpable breast tissue, a minute uterus and only a trace of pubic hair. Treatment for some months with a high dosage of oestrogen caused her breasts to develop, pubic hair to grow and her uterus to increase in size. Soon after uterine bleeding occurred. Treatment was changed from continuous to cyclical, and after six regular periods oestrogen (withdrawal bleedings had occurred) was stopped. The periods remained almost regular. Two years later (three years from the beginning of treatment) she married and within four months was pregnant. Her baby is due next April. It is possible that I am committing the *post hoc propter hoc* fallacy, but I don't think so.

Mr Bourne is also too dogmatic in his remarks about the use of androgens in metropathia. Though it is certainly true that a high proportion of patients must ultimately come to x-rays or hysterectomy, many severe cases can be kept in good health by an occasional course of methyl testosterone which is comparatively cheap and which does not produce virilism in the dosage required. A few milder cases make a complete and apparently permanent recovery. Hysterectomy is far too often performed in cases of menorrhagia. No harm is done and much unhappiness is avoided by a preliminary trial of medical treatment. I feel sure that Mr Bourne, whose work with Lord Moran on the use of thyroid extract in the menorrhagia of puberty must have saved many young girls from hysterectomy, would be well advised to give a further and perhaps more energetic trial to the use of methyl testosterone in the menorrhagia of riper years—I am, etc.

London W 1

RAYMOND C

Chronic Middle Ear Suppuration

SIR—I think that a description of treatment of chronic middle ear suppuration by a very simple and efficient method is worth while. These cases can be divided into two classes: (1) Cholesteatoma (2) Other chronic cases of otitis media—I am not considering such conditions as malignant disease, tuberculosis, etc. The nature of the discharge is of some importance—that is, whether it is mucoid or purulent—but a condition of great importance is the odour of the discharge. There may be no odour, these cases are amenable to simple treatment. On the other hand the discharge may have an offensive odour, which may be either the nauseating stink of a true cholesteatoma or simply a bad smell from putrefaction. Chronic middle ear suppuration is of course primarily due to infection from the upper respiratory tract, including the nasal accessory sinuses, and proper care of these conditions is essential in treatment. However, there are other factors of importance such as the general health, the patient's constitution, family and economic considerations—these conditions all require attention.

Doctor and patient should both fully understand that the essence of treatment is to keep the ear clean and dry. It must also be realized that in the presence of a perforation of the tympanic membrane unless the Eustachian tube is completely obstructed reinfection of the middle ear is constantly recurring and is inevitable when sepsis from the upper respiratory areas is forced into the middle ear by blowing the nose etc. If the perforation is completely sealed then this "through channel" of infection is eliminated. The size of the perforation has little bearing on the actual treatment, if the perforation is so small that the tympanic cavity cannot be easily treated it means that the suppuration is very mild and will recover itself if permitted, if the perforation is larger, access to the tympanic cavity is facilitated.

The first step is to eliminate the odour, and this can be done by thorough mechanical cleansing, and in doing this the shape of the auditory canal must be realized. Patients can be instructed to do this by the method taught by Prof. Neumann of Vienna: rolling a small fine pointed cone of wool about 1 in. (2.5 cm) in length and gently tucking this into the canal, repeating until every corner is cleansed properly, and then instilling one or two drops of alcohol. This is done as often as is necessary to keep the ear clean and dry, it is a safe method, is ideal for children, and the patient's friends can be taught. In a week or ten days if properly carried out, the odour, except in the presence of cholesteatoma, will have gone, and the next line of treatment is used. This consists of what I call the "pipette and powder" treatment, and again the patient's relations can learn to carry it out.

The patient lies on the side with the ear to be treated directed upwards. The ear is carefully mopped out, and then irrigated with aqueous solution of acriflavine (1 in 1,500) by means of a rubber-capped pipette. By squeezing and releasing the rubber cap the tympanic cavity is gently washed out, unless the perforation is so small that it is unnecessary. A few pipettefuls of acriflavine will cleanse the cavity. It is now carefully but thoroughly dried once more, and the ear canal is filled with powder which is actually tamped well into the canal and then a small pledget of gauze inserted to prevent the powder from falling out. The nature of the powder is of minor importance, it is not the chemical action of the powder that is important but the mechanical "corking" of the perforation to prevent infection being forced into the middle ear. I have used plain boracic powder, boracic and iodine powder, penicillin and sulphanilamide powder. The results are the same. Plain boracic powder is "lumpy" and not so easy to manipulate. Penicillin and sulphanilamide powder is a fine dry powder easy to use, but may be followed by an allergic dermatitis. Boracic and iodine powder (0.1% iodine) is a good powder, but occasionally a patient is sensitive to iodine.

If discharge persists the powder will quickly be softened, and to the non expert gives the appearance of profuse pus. In such a case it is necessary to repeat the treatment until the powder is found to remain dry. When the powder remains dry all that is necessary is to put in more powder as often as necessary to keep the ear filled. This "cork" or "plug" of powder is kept in the ear for three months or more, but it must on no account be allowed to be wetted—it must be kept clean and dry. After three months the powder may be allowed to disintegrate. It interferes very slightly with hearing after the first few days. It is surprising to find the number of even fairly large perforations that are found healed when this powder eventually disintegrates. I have not used this method with a genuine cholesteatoma but then genuine cholesteatoma is becoming rarer, being merely a result of neglect or wrong

ful treatment, the best treatment is prevention. The 'pipette and powder' treatment is equally applicable to the later stages of acute otitis media, which is the precursor of chronic otitis media, and which is so often prolonged by reinfection by means of the 'through channel' nose blowing, etc.

Once more I wish to stress the point that in the conservative treatment of chronic middle ear suppuration it is necessary to realize that the condition is much more than just a localized infection in an area which appears to be somewhat difficult of access. When properly administered the sulphonamides and penicillin are of considerable value, but their use does not prevent reinfection, and the principles enunciated—namely, the keeping of the ear clean and dry and the prevention of the "through channel" of reinfection—must be observed—I am etc.,

Brisbane Queensland

ERNEST CULPIN

Limb Haemangiectasis and Cirsoid Aneurysm

SIR—In regard to examples of the association of developmental haemangiectatic hypertrophy of limbs associated with cirsoid aneurysm I think there is still a tendency to regard the cirsoid aneurysm as the cause of the limb enlargement instead of recognizing that both conditions are due to some developmental abnormality, probably during early intrauterine life in the nervous regulation of the blood supply and nutrition of the affected part. Certainly the same type of limb enlargement occurs in the absence of any actual cirsoid aneurysm. Typical cases are distinguished by increased length of long bones in the affected extremity, often there are vascular hamartomata in the affected extremity some times in other parts of the body. The bony enlargement seems to be connected with increased arterial blood supply possibly associated with increased size of the nutrient artery. Occasionally apparently similar cases are met with in which no enlargement of long bones can be made out. Can it be because in such cases the nutrient blood vessels of the bones are not involved? Sometimes parts of the body other than limbs have been similarly affected by what one may term 'haemangiectatic hypertrophy'. Some cases of hemihypertrophy appear to be the result of a similar developmental agency. Probably the rare cases of monstrous "true gigantism" of fingers, toes, hands, or feet are due to a somewhat different developmental agency.

My excuse for writing this letter is that I have taken continuous interest in the subject since my article on "Haemangiectatic Hypertrophy" in 1918 (*Brit J Child Dis* 15, 13). Since then my name has frequently been attached to the syndrome in Britain and other countries as well as the name of Klippel, who stressed the 'osteo hypertrophic' changes associated with the dilatations of blood vessels (cf also F P Weber "Angioma Formation in connexion with Hypertrophy of Limbs and Hemihypertrophy," *Brit J Derm Syph*, 1907, 19, 231).—I am, etc.,

London W 1

F PARKES WEBER

Erythroblastosis Foetalis and Breast-feeding

SIR—The case report by Dr Rosemary Davies (Jan 25, p 138) of a breast-fed child with erythroblastosis foetalis in which recovery followed the cessation of breast-feeding calls for some comment. The recovery may well have been due to the transfusion of 170 ml of blood—about one half of the child's total blood volume—two days after the institution of artificial feeding. It is also well known that infants who for some reason have lost much blood frequently require more than one transfusion before recovery occurs.

It has been repeatedly shown¹ that small quantities of protein, capable of producing immunity responses and thus presumably undigested, are absorbed in infants and hence the theoretical possibility that agglutinins could be absorbed from breast milk. But the amount of undigested protein absorbed in this way is minute compared with the total quantity ingested and digested and it would be surprising if of the agglutinins present in breast milk sufficient could be absorbed to be of any clinical importance. The presence of Rh antibodies in breast milk does not necessitate their absorption and as far as I am aware no direct evidence of the intestinal absorption of Rh antibodies has been recorded. It would be a very great pity at our present

Vitamin Therapy

- its uses and limitations

CONVALESCENCE

The period of debility following acute illness—as, for example, influenza and pneumonia—calls for special care because of the tendency to relapse and the lowered resistance to other infections. Modern work indicates that this state is due in no small measure to depleted reserves—sub-normal nutrition from the restricted food intake during illness and to the increased utilisation of certain food factors during infection.

COMPLEVITE

**A single supplement
for multiple deficiencies**

The recommended daily dose provides —

Vitamin A	4,000 i.u.	Iodine	} <i>not less than 10 p.p.m. each</i>
Vitamin D	300 i.u.	Manganese	
Vitamin B ₁	0.6 mg	Copper	
Vitamin C	20 mg		
Calcium	160 mg		
Iron	68 mg

GOOD RESULTS—EVEN IN ADVERSE CONDITIONS

Ensign STANDARD X-RAY FILM

Fine definition, excellent contrast, sparkling cleanliness—these are obtained by the use of Ensign Standard X-Ray Films—even when conditions in X-ray room and dark room are not favourable. The film has normal speed and exceptional latitude. The finest definition is obtained because of the freedom from fog. Variations in exposure times can be adjusted in development without materially affecting the quality of the finished radiograph. Whenever speed is not of primary importance Ensign Standard will achieve the desired results.

LIVOGEN

Trade Mark

The recent cancellation of the Liver Extract (Regulation of Use) Order, 1945 (b), makes it possible for Livogen once again to be prescribed freely and without restrictions upon its use.

Livogen is accordingly now available, it is made to the same formula as that used up to 1941, as follows —

FORMULA

Each fluid ounce contains

LIQUID EXTRACT OF YEAST	Equivalent to 2 oz of fresh yeast
LIQUID EXTRACT OF LIVER	$\frac{1}{2}$ fl oz
VITAMIN B ₁	Sufficient to produce a total of 400 international units
NICOTINIC ACID	An appropriate quantity for prophylaxis

Modern Salicylate Therapy

ALTHOUGH acetylsalicylic acid is one of the most popular and effective non-narcotic analgesics available its use has frequently been discarded by the physician in view of the possibility of its irritating the gastro intestinal tract.

'Alasil' however helps to overcome this objection by providing the beneficial therapeutic effects of acetylsalicylic acid in such a form that it is acceptable even by delicate or disordered digestions. This tolerability is due to the fact that 'Alasil' combines acetylsalicylic acid with Dibasic Calcium Phosphate and 'Alocol' an effective gastric sedative and antacid.

For these reasons 'Alasil' is an analgesic antipyretic and anti-rheumatic which can be administered with complete confidence in all the conditions in which such an agent is indicated. It is so well tolerated that its use can be pushed to the desired extent.

Alasil

A supply for clinical trial, with full descriptive literature sent free on request.

A. WANDER LTD London SW7 M321

Each tablet contains 5 grs Acetylsalicylic Acid 6 grs 'Alocol' (Colloidal Aluminium Hydroxide) and $\frac{1}{2}$ grs Dibasic Calcium Phosphate

Women Doctors and Service Specialist Appointments

SIR,—The Medical Women's Federation has been informed of the extreme difficulty which is being experienced in finding replacements from civilian life for the specialists (men and women) in the Services whose release is behind all other medical personnel—in the Army for instance, it is 12 groups behind. There is at present no conscription of women. As many women doctors know in June 1945 the Ministry of Labour by a Cabinet decision abandoned the call up of women and the doctors were included in the general ruling. The Medical Women's Federation wrote a letter at the time to the Ministry of Labour which was afterwards reported in the medical Press, pointing out that this exemption was contrary to the wish of medical women, it deplored the position and said that in professional matters women doctors wished to be treated as doctors and not to have special privileges as women. Similar representations were made by the Services themselves and by the Central Medical War Committee. The Ministry of Labour, however, was not willing to rescind the order as applying to women doctors, but pointed out that they were at liberty to volunteer.

It must be admitted that recently the Service intake of volunteer women doctors has been very small. This has had the unfortunate consequence of delaying the release of serving specialists both men and women, and of necessitating the call-up of an unfair proportion of men doctors many approaching 40 on whom it may inflict serious hardship. Young women of the graded or full specialist class must realize furthermore that their immunity from conscription is certainly not entirely to their advantage. B1 posts and higher hospital appointments are being reserved to a great extent for returning Service doctors or for those who are "recruitable" in order that, in the latter case, there shall be some specialists trained in due course to replace those who are now going into the Services.

The Medical Women's Federation wishes to draw the attention of all young women specialists to this urgent need, recognizing however that this is only a short term measure. Long-term policy involves the consideration of the conscription of women doctors equally with men but this is bound up with the rectification of certain anomalies in the status of medical women serving with the Army and R.A.F. In spite of this however, the Federation urges eligible women specialists to offer their services now chiefly for the sake of those who are being retained unwillingly or called up and perhaps also for their own sakes as, on leaving the Services they will be in a strong position in applying for further appointments—I am, etc.,

Food for Invalids

SIR—I have been reading the interesting debate in Parliament on Jan 22 (*Journal* Feb 1, p 204) on this subject. The accounts given by the *British Medical Journal* and by the *Lancet* are substantially the same, with one very important exception. The following paragraph which appears in the *Lancet* does not appear in the *British Medical Journal*:

Mr S. Hastings asked the Minister if he would give figures to compare the amount of priority milk ordered by doctors in residential areas such as Bath, Bournemouth, Hove or Hampstead with that in industrial areas like Tyneside or South Wales. Mr Strachey in December 1946 the number of domestic consumers obtaining priority milk on medical grounds per thousand of population was: Bath and Bathaven 31, Bournemouth and Christchurch 38, Hove and Brighton 33, Hampstead, 47, Tyneside, 15, S. Wales 15.

I am not for the moment concerned as to what is the explanation for the interesting fact that there are more than three

times as many persons receiving priority rations in Hampstead than in Tyneside, but it would be interesting to know why the *British Medical Journal* omitted to report this question and Mr Strachey's answer to it—I am, etc.,

University of Manchester

ROBERT PLATT

* * Because our Parliamentary correspondent did not report the passage quoted above, presumably in order to allow space for a fuller report of other matters excluded from the pages of the *Lancet*—ED. B.M.J.

Non-agenized Bread

SIR—I care not for the finer points in the differential diagnosis of hysteria in dogs, neither would I wish to dissuade white-bread eaters from consuming agenized flour—bleached with NCl_3 —should they so wish to do. I have however a foolish personal prejudice against eating bread made from flour which produces fits, whether hysterical or not, in dogs and which may cause their death after a few weeks.

Is it possible now to obtain bread made from plain whole meal, not improved in any way and with no extraneous substance added or none of the whole meal removed? Is there any easy test one could apply to make sure that the flour has not been improved—something like the 'starch and iodide' test for free chlorine? Finally, Sir, I should be grateful for information as to where, pending any action which may be taken by the various ministries concerned, I can obtain guaranteed non-agenized bread in the London area—I am, etc.,

Harrow Middx

W. MUNRO LESLIE

Endogenous Depression in General Practice

SIR—I first hasten to inform Dr A. L. Rowson (Feb 15, p 271) that my question was asked in good faith and was not intended to be either rhetorical or rude. I did not realize that he had had institutional experience in psychiatry. I imagine that all who work in mental hospitals would be glad to see both change and development. Many experienced psychiatrists have in fact practically pleaded for certain improvements, and I see no objection to a Royal Commission.

But as I do not think that things are as bad as Dr Rowson would have us believe I would take up a few of his points and emphasize some safeguards. The first is the increasing use of admitting patients without certificates, either as voluntary boarders or temporary patients. No one is allowed to detain a voluntary boarder for more than three days after he has given in his notice to quit, so if either the patient or his relatives think he is unhappy, or not making progress, he can go.

Then as regards E.C.T., this is never given or continued without the patient's consent, and if no progress is being made the treatment is stopped. I simply do not understand the statement—no reference being given—that patients fear electrical convulsions, though this was not uncommon when chemical convulsants were in use. Is Dr Rowson perchance thinking of intravenous cardiazol or its analogues? In any case the patient can always refuse a second treatment. Nor I submit is E.C.T. customarily given without previous psychotherapy and diagnosis. The development of the clinic to which the doctor either brings or sends his patient has great possibilities and let us hope, will be used more frequently still—I am, etc.,

Cambridge

A. KNYVETT GORDON

* * This correspondence is now closed—ED. B.M.J.

Treatment of Patients

SIR—Dr Kenneth Sheldon (Feb 1, p 195) drags up the old, old accusation that there is one law for the private patient and one for the panel. He talks about the proud boast of the principal has been how many patients he could dispose of in the hour. Why not? Surely patients have no wish to sit for hours in a doctor's waiting-room while the latter spends twenty minutes on each case of impetigo or scabies?

One can very easily dispose of say fifteen cases of "repeats" of medicine, certificates, injections and short "spot diagnoses" in from half to three-quarters of an hour—and these are what the bulk of our surgeries consist of—and inform the others that their case may take some time to go into and that it would be preferable to do it in their own homes at their own bedside.

At a time when parts of the lay Press are more than usually critical of our profession it seems a pity that these accusations are made by our own colleagues against men and women who also 'like time to examine their patients,' but do not always find it necessary to exalt their own "professional consciences"—I am, etc.,

W A BELLAMY

Diet and Canine Hysteria

SIR,—Pyridoxine—vitamin B₆—(*J Nutrit*, 1938, 16, 197) is essential to the dog. Deficiency causes convulsions like epilepsy, dermatitis, and a microcytic hypochromic anaemia (*Amer J med Sci* 1940, 199, 518). Treatment with pyridoxine cures. May not this be the cause of canine hysteria or epileptiform fits referred to in Mr Hamilton Kirk's letter (Feb 1, p 200)?—I am, etc.,

Blyth Northumberland

A G NEWELL

Eye Surgery

SIR,—I believe there is no doubt as to the validity of the justification which Mr H B Stallard puts forward (Feb 1 p 200) for his views on Kronlein's operation and for his statement with regard to the relative radiosensitivity of glioma of the retina as compared with a malignant melanoma of the choroid. Mr Stallard has taken advantage of opportunities of performing Kronlein's operation which few have had. It is an operation which is not often called for, and I do not doubt that many ophthalmic surgeons of wide experience have never performed it. Mr Stallard has done a service by bringing forward the advantages and scope of the operation and by describing the technique so clearly.

I should have thought there was no doubt as to the accuracy of the statement 'Malignant melanomata of the choroid are not so radiosensitive as glioma of the retina.' The manner in which a retinal glioma can be watched to disappear with the ophthalmoscope is quite remarkable, and the fact that, as Mr Stallard says, 'A retinal glioma has disappeared, and there have been no recurrences in periods up to fifteen years after irradiation, some useful vision has been retained and the child's life saved' would seem to justify the use of the term 'cure'. A number of cases of malignant melanoma of the choroid have been treated by radium, but I believe none has shown a comparable result.—I am, etc.,

Salisbury

R FOSTER MOORE

Prevention of Rust on Instruments

SIR,—With reference to the question and answer under the above heading (Jan 25, p 168), the inquirer asks whether any substance can be added to boiling water to prevent rusting of instruments during sterilization. The reply is substantially that there is no time for appreciable rusting to occur during this process. This statement is incorrect as regards cutting instruments made of a high carbon steel, for example cataract knives, whose edges are rapidly spoilt by corrosion when boiled in 2% Na CO₃. While complete protection during water boiling cannot be achieved without using solutions of ammonium or sodium hydroxide (whose carry-over at even small dilutions might damage an eye), it is possible to reduce boiling corrosion to negligible proportions by the use of 2% A C 10 emulsified in a 2% w/v Na CO₃. 10H₂O solution in water (*vide Foster, Le May and Johnstone Proc roy Soc Med* 1945 38, 465). A C 10 consists of 95% of a light petroleum neutral oil and 5% of a complex of sodium salts of petroleum sulphonic acids.—I am, etc.,

Leeds

JOHN FOSTER

History of Arab Medicine

SIR,—Had your correspondent, I B George (Feb 1, p 202), been a little better acquainted with the literature of his subject, he would have known that Dr Neligan was summarizing (Dec 14, 1946 p 919) a passage from the late Prof E G Browne's *Arabian Medicine* (Cambridge, 1921, p 2). Here it is

'When we speak of 'Arabian Science' or 'Arabian Medicine' we mean that body of scientific or medical doctrine which is enshrined in books written in the Arabic language, but which is

for the most part Greek in its origin, though with Indian, Persian, and Syrian accretions, and only in a very small degree the product of the Arabian mind. Its importance, as has long been recognized, lies not in its originality, but in the fact that in the long interval which separated the decay of Greek learning from the Renaissance it represented the most faithful tradition of ancient wisdom, and was during the Dark Ages the principal source from which Europe derived such philosophical and scientific ideas as she possessed.'

Most handbooks of the history of medicine say much the same thing, but it might be objected that most of their authors were not well acquainted with Arabic literature at first hand. Prof Browne was

Were it not for your correspondent's onslaught on the late Dr Neligan, one might take his letter for a hoax. Thus he assures us that the Christian Church regarded belief in infection or contagion as heretical, that only a Moslem physician dared to say that the 'black death' was spread by infection and contagion and that he anticipated Pasteur by five centuries. Well, the best contemporary account of the epidemiology of the pestilence of 1347-9 was that of Guy de Chauliac who observed it in Avignon, his account is reprinted in Haeser's well known *Lehrbuch* (vol 3, pp 175-6). According to de Chauliac the disease "was so contagious, particularly when there was blood in the sputum (italics mine), that not only by staying with the patient but by merely looking on him one took the disease from another, so that people died without nurses and were buried without priests." Guy de Chauliac was neither a Moslem nor a heretic, but the Pope's own surgeon. The words I have italicized show him to have been a good observer. The plague broke out at Avignon in January, 1348, and was at first primary pneumonic plague. Later in the year it was clinically bubonic plague. The former is of course infectious from person to person the latter not. It would be interesting to know when the Christian Church decided that it was heretical to believe pestilences were contagious. Isidore, who was, I think, a bishop, roundly stated (about 700 years before the 'black death') *Pestilentia est contagium quod, dum unum apprehenderit celeriter ad plures transit*. It is hardly necessary to say that what Galen, Isidore, de Chauliac, and the Moslem physician understood by contagion or infection had no relation to Pasteur's doctrine of *contagium vivum*. The analogy is with the conduction of an electric current or, better, with the sympathetic vibration of a tuning fork picking up its fundamental note. It was, as Prof Singer pointed out more than thirty years ago, the Italian physician Fracastorius who first took the step of postulating a living contagium. Very few of his contemporaries realized the importance of his suggestion, but, as he dedicated his book to a cardinal, the notion was not regarded as heretical.

I suggest that Dr Neligan was a good deal better acquainted with the history of medicine than your correspondent.—I am etc.,

MAJOR GREENWOOD

Colonial Medical Service

SIR—In recent months a number of disparaging letters from members of the Colonial Medical Service have appeared in your *Journal*. Obviously the facts stated were true of particular cases, though they would appear to portray one side of a picture only, to the entire exclusion of the other. These letters might easily have turned me from my decision to join the Service had not I applied out of some sense of vocation.

As a very junior member of the Service, though not so young in the profession, I am not qualified to make generalizations, but for the sake of those who might be deterred in their choice of a career I will record briefly some of my first impressions of work in Africa. Although in a relatively remote out station, I have found ample scope for my bent which happens to be surgery, and am already experiencing the truth of a statement made to me on my way out to the effect that "your work will be just what you make it. The natives will soon discover your bent and your abilities or shortcomings, and every case successfully dealt with will inevitably produce two more. This generalization refers equally to preventive medicine, and some of my predecessors have left indelible memorials written on the landscape.

Admittedly administration can be irksome when one would rather give one's time to other calls, but ample time in one's

programme can be made for clinical work. Facilities are primitive compared with home standards, and although a photograph of an English theatre is liable to produce a mild nostalgia there is a definite satisfaction to be found in improvising and "making do." A medical officer is expected to practise everything relating no matter how remotely, to his profession but each has his own bent, and in my short experience I have not been disappointed by lack of interesting work. One of the great sources of satisfaction is that with much material at hand one can select for hospital treatment only those for whom improvement or cure can be almost guaranteed. How different to many of the patients who take one's time in dispensaries at home. All I have written refers to the only station of which I have experience, but I trust it will serve to illustrate that there are localities in which a doctor prepared for a relatively lonely existence will find life not only fertile with interest but offering much compensation, rather in the knowledge of suffering relieved than in salary increments—I am, etc.,

EAST AFRICA

* * This correspondence is now closed—ED, BMJ

POINTS FROM LETTERS

National Health Service—Dr A E CLAYTON (Shrewsbury) writes: "The vocation, aims and work of a doctor may be expressed as follows: (1) To assuage human suffering and misery both of body and mind, however caused, with a view to the restoration of health; (2) failing the latter, to make the conditions of living as tolerable and pleasant as possible. These are simple words but they cover an immense field. To accomplish these aims certain values ought to be paramount—for example, there is the value of a doctor's sympathy with his patient particularly when issues of life and death are at stake, his sense of unity with him in the sharing of a common heritage. These are the values integral to an enlightened humanitarianism, the values of the Christian ethos, with all they imply, the value of a patient's belief and faith in his doctor. Are these values denied? If so then I don't think it much matters which framework you have for a health service or any other activity."

Within the chamber of human conflict with disease and in many other situations the State is not competent, and never can be to assess the values and control the operations of the human spirit. In the sixteenth century the issue was King v Parliament; in 1947 it is the State; the integrity of the human personality. The profession, though it may not know it, is 'the thin red line,' and whether we know it or not the public certainly does not.

Dr L LEY (Great Yarmouth) writes: "I would ask the members of the BMA if they are prepared open-eyed to surrender themselves and the profession to Government muddle and mismanagement. It is perfectly certain that if half or even a third of the GPs in the country refuse to work the Act it must be utterly unworkable by the remainder, and will be completely discredited."

The Need is Unity—Dr J B DAVID (Trebetherick, Cornwall) writes: "What strikes a comparative newcomer to the arena of battle is the apparent disunity among the profession. Can it be wondered that abroad we thought in so muddled a fashion and called the BMA leaders obstinate old reactionaries? We were not convinced of the implications of anything. As things are at present there is no inducement to the Minister to have one iota of the Act altered: he believes probably rightly that he only has to start the scheme and nearly half the profession will enter at once. Of a truth the doctrine of 'divide and rule' has come home to us with a vengeance. What are we to do? I do not know. But unless we can become more united as a profession and are able to produce an 80% No we shall find ourselves passing down the broad and easy road to slavery."

An 84 hour Week—Dr R DINGWALL KENNEDY (Edinburgh) writes: "Dr Gerald Rosemont's suggestion (Feb 8, p 233) of an 84 hour week for GPs calls for certain amendments."

Who will take his calls when he is out? I am not quite clear what is meant by this question. From what follows in Dr Rosemont's letter it would appear to mean: Who will answer the door, telephone, etc? And if that is so the answer is simple: the same person or persons doing so now unless and until the promised clinics are forthcoming and the doctor's house becomes, for the first time in history, his castle. If on the other hand the question really asks who will act as locum in emergency calls the answer is not to be found in an 84 hour week. If a night-duty rota can be arranged so can a half-day and holiday rota. During the war many small medical communities worked out their own self help scheme."

Obituary

THOMAS WILLIAM SHORE, OBE, MD

A link with the St Bartholomew's of the last century has been severed by the death, on Feb 19, at the age of 85, of Dr T W Shore, whose close connexion with the hospital and school went back for sixty years.

Thomas William Shore was born on Nov 5, 1861, and was educated at Burnley Grammar School and at Hartley College, Southampton. Coming to London at the age of 18, he entered Bart's with a scholarship in science. Many prizes fell to his lot during his student career, including first-class honours in zoology and botany. St Bartholomew's in the early 'eighties was a very different place from to-day, though it was equally stimulating, and its teachers and clinicians, while fewer, were equally renowned. It was before the advent of the telephone or the motor-car, and Shore used to recall that when a member of the staff was wanted at night a porter was sent in a hansom to fetch him. The number of students was not smaller than it would be now in a normal year but the visiting staff numbered only twenty—four full and four assistant physicians, a corresponding number of surgeons, two physician accoucheurs and two ophthalmic surgeons.

1 Topical Press

It was a brilliant staff and included several men who later became presidents of the Royal Colleges. At this time too "Barts" was almost a forcing ground for medical baronets. Shore was house-physician to Samuel Gee, an outstanding teacher at the bedside, whose aphorisms were collected by another of his students. In those days a house-physician was appointed for a full year.

In 1884 the year after he qualified, Shore was made assistant demonstrator in physiology, and after four years became full demonstrator, an appointment always considered a stepping-stone to the medical school staff. From 1886 onwards he was lecturer in comparative anatomy, and in 1892 when the medical curriculum was enlarged to a five years course, he became lecturer in biology. These lectureships he retained until 1909 and there are many who recall him as a singularly able teacher. His biology lectures were illustrated by some most graphic work on the blackboard, and it has been said that his drawings of the division of cells and the development from the cell to the adult stage were as enlightening as Cantu's famous film, and even more instructive because they were slower.

In 1891 he became warden of the residential college, a post held when Shore himself was a student by another famous son of Bart's Sir Norman Moore. He occupied the house to which Sir James Paget once brought his bride. This position with the secretaryship of the School, Shore held until 1898 and in it he revealed his great ability as an educationist and administrator. His reign as dean began in 1906 and ended with his retirement in 1930. Great changes took place in the College and the Hospital during this period—the completion of the library, the building of the dissecting-room, the establishment of new lecture theatres, biological laboratories (his special interest), the out-patient department, the surgical and pathological blocks and the nurses' home.

Shore gave the best of his strength and affection to St Bartholomew's, but he found time for a good deal of work outside. In 1919 he was made a member of the Consultative Council of Medical and Allied Services. For a short period he was examiner in natural history to the University of Aberdeen and for longer periods examiner in the same subject to the Army and the Indian Medical Services and in biology to the Royal College of Surgeons. For as long as eighteen years he was

in science to the Naval Medical Service. He helped the British Medical Association to which he was originally elected in 1894, on some headquarters committees, including the Central Medical War Committee of 1914-19, to which he gave invaluable service as chairman of a subcommittee. When the Association met at Cambridge in 1920 he was vice president of the Section of Medical Education. In addition to numerous articles in the scientific journals he wrote a book, *Practical Biology* published in 1887. One of his sons by his first wife is Dr T. H. G. Shore, of Plymouth.

In his retirement Dr Shore lived first at Upper Norwood, within easy reach of his old haunts. The news of his death, which we recorded briefly in our issue of March 1, will be received with sadness by innumerable old Bart's men, who remember him with gratitude both for his patience and skill as a teacher and for his labours for medical education in general.

PIERRE JANET, M.D.

Pierre Janet has died in Paris at the age of 87, and the world has lost one of the greatest clinicians of our age in psychological medicine. A pupil of Charcot, he had learnt to recognize the existence of psychogenic disorders as distinct from physical, for Charcot had experimentally reproduced under hypnosis disorders like hysterical paralysis. No one has had a wider experience than Janet of such disorders, nor was there a more acute observer. His descriptions of the clinical manifestations of these disorders surpass in extent and accuracy anything that we have elsewhere.

Janet's ideas as to the nature and origin of the psychoneuroses based as they were on his earlier philosophic studies, are the common sense theories most acceptable to the ordinary medical practitioner especially as he fulfils more than any other clinician of the past the modern demand that the human personality of mind and body should be treated as a unity. He viewed the personality as a synthesis of all our impressions and experiences in life. At any special time we have a certain amount of vital energy. If that energy is at a high level the personality functions as a synthesis we feel fit for anything and capable of meeting all our responsibilities in life, if at a low level we shrink from life and feel it a burden even to entertain a friend. The psychoneuroses are due to a lowering of the psychological level so that the personality ceases to function as a whole. When there is simply a lowering of psychological tension the personality is enfeebled, so that we have the condition of psychasthenia (obsessions, neurasthenia etc.) with indecision, lack of adaptation, and withdrawal from reality. (We all know that we are more liable to neurotic reactions when we are run down.) In other cases the tension is so low that the personality instead of maintaining itself as a synthesis falls apart, in which case there appears dissociation or splitting of the personality as in hysteria somnambulism, and so forth.

Janet's theory of dissociation, therefore, differs from that of Freud. In Janet's view it is the result of lack of energy to hold the personality together, whereas according to Freud dissociation is due to active repression of what is unpleasant. The lowering of psychological tension is sometimes constitutional, sometimes due to illnesses, sometimes due to emotional strain or to psychological causes like worry. It is this linking up of the physical, emotional, and psychological factors by Janet which appeals to the ordinary physician as being philosophically sound 'common sense' and it is surprising that he has not more adherents in the medical profession in this country. But the great vogue of Freud, and his derivatives, is probably to be found not only in his deeper investigations into the causes of neurosis and their purposive nature but in the fact that his methods have secured better therapeutic results than those of Janet. Both of them revived the original trauma which caused the hysterical symptoms both (at first) used hypnosis to do so and both got emotional responses, but Freud got results by his method of abreaction while Janet was not so successful. We can only suggest that this difference was due to the fact that while both revived the experience and the emotion Freud linked it up with the conscious mind by getting the patient to 'talk it over' afterwards with the result that the dissociation was 'reduced' whereas Janet does not appear to have done so so that both the dissociation and the symptom

persisted. But psychoanalytic theories would be none the worse for some of the balance of Janet's philosophic views which are at the same time practical and convincing. Let us hope that Janet's death may stimulate in this country a renewal of interest in his works which are well worthy of study.

Pierre-Marie Felix Janet was born in Paris in 1859 and took his degree in philosophy in 1882, and his M.D. in 1893. He was attached to the Salpêtrière, and then appointed to the University ultimately becoming Professor at the Sorbonne from 1898-1902. From then onwards he devoted most of his life to research, became President of the Académie des Sciences Morales et Politiques in 1925, and gave many lectures abroad.

J. A. H.

Dr ANDREW PATERSON died suddenly on Feb. 11 at the age of 40. Only three months ago Dr Paterson had been appointed a senior physician at the Maudsley Hospital Postgraduate Medical School, London. He qualified at Edinburgh in 1935 and proceeded M.D. in 1942. In 1938 he was appointed assistant in research in psychiatry to the Regius Professor of Physics at Cambridge.

Mr O. L. Zangwill writes from the Institute of Experimental Psychology at Oxford: 'As research psychologist to the Brain Injuries Unit in Edinburgh during the war it was my privilege to work for some years in very close association with the late Dr Andrew Paterson. Perhaps, therefore, I may be allowed to pay a brief tribute to his outstanding qualities as a research psychiatrist. Andrew Paterson combined remarkable clinical acumen with a deep concern for the fundamental problems of psychology and philosophy. His interest in the theory of knowledge, bred of an early training in philosophy, led him to seek in the psychological analysis of the effects of brain injury a key to the basic problems of perception and thought. In developing his ideas, moreover, he was ever prepared to welcome the co-operation of all whose interests lay along lines similar to his own. Towards experimental psychologists in particular his attitude was one of unfailing sympathy and co-operation. He was one of the all too rare clinical psychiatrists who take seriously the problems and methods of experimental psychology. By Andrew Paterson's premature death not only has British psychiatry lost one of the most distinguished of its younger practitioners but general psychology is the poorer for the loss of a devoted ally and fellow traveller. His memory will remain an inspiration to all who see in the elucidation of brain mechanisms the most fruitful approach to the fundamental problems of human experience and conduct.'

Dr ELIZABETH HAMILTON BROOK died in an Edinburgh nursing home on Feb. 22. She qualified M.B., Ch.B. at Edinburgh in 1906 and took the D.P.H. in 1910. In 1915 Dr Brook was a member of one of the teams of doctors and nurses sent out by the Scottish Women's Hospitals to Serbia. She rendered valuable service there under the leadership of Dr Elsie Inglis. Most of her work was done at Kragujevatz where typhus cases were arriving in large numbers every day. On returning to this country Dr Brook continued to work in the public health service in Lancashire until her retirement some years ago.

Dr G. A. Auden, Threlkeld, Cumberland, writes: 'May I be allowed to correct a printer's error in the obituary notice of Dr BRICE COLLYER (Feb. 1, p. 203)? Langdon Down should be Langdon-Brown, who succeeded Horder as house physician to Dr Samuel Gee. I think too that it was not James Berry but his brother Arthur who was his contemporary at Whitgift School, for the former was senior to Collyer by ten years. Arthur Berry was senior wrangler in 1886 and was elected a Fellow of King's College, Cambridge. Another contemporary and close friend of Collyer's was W. M. Geldart who became a Fellow of All Souls and Vinerian Professor of English Law at Oxford. It was my privilege to enjoy his friendship since he was Gee's house-physician in 1894. At that time he had two great heroes—Cromwell and Napoleon a drawing of whose bust hung over his mantelpiece in his rooms. But his interests were many and diverse combined with a remarkably accurate memory. He was never tired of quoting the terse and characteristic sayings of Dr Gee. When I spent a few days with him immediately before Christmas he repeated long pieces from Wordsworth, Tennyson and Shakespeare without hesitation and with manifest enjoyment. This accuracy of memory extended to his clinical work and thus enhanced his powers and acumen as a physician. He greatly enjoyed travelling abroad to South Africa and the Mediterranean and on the Continent with his wife whose sudden death in 1941 broke a very happy and close companionship and left a terrible gap in his life.'

ACTIVE AT BODY TEMPERATURE...

When an Anusol Suppository is placed on a piece of plate glass and heated slightly it will resolve and spread evenly. This demonstrates graphically how Anusol Suppositories melt at body temperature to form a fine emollient film that lubricates the affected rectal area. Thus by their soothing action friction is minimized and congestion subsides. Prompt relief follows marked by genuine symptomatic improvement for Anusol Suppositories contain no narcotic or anaesthetic drug that might mask symptoms and give a false sense of security.

CAMBRIDGE NEW PORTABLE CARDIOGRAPH IN LEATHER CASE

Size 20 x 9 x 11 ins
Weight only 30 lb
(complete with rectifier
and all accessories)

A COMPLETE CARDIOGRAPH IN A SUITCASE

This new instrument embodies the characteristics developed in Cambridge Cardiographs through many years. The records—on a continuous paper roll—are in every way comparable with those of existing outfits. An ideal instrument for consultants and practitioners. Orders now accepted for delivery in strict rotation.

May we send descriptive leaflet No J-263?

Hepolon is produced by special processes which conserve all the known hæmatopoietic principles of the whole liver. It approximates to the extract described by Gänsslen.

Hepolon not only passes the highest clinical tests for potency against pernicious anaemia but contains Whipple's factor, Wills's factor, riboflavine, nicotinic acid, and the hæmatonic minerals of liver; it gives no reactions for histamine or undesirable protein matter.

Ampoules of 2 c.c. box of 5.6 box of 12 11/6 and box of 24 22/-
Rubber-capped vial of 10 c.c. 6 and of 30 c.c. 12 6.

Ribena therapy for the anaemias

That the presence of vitamin C plays an important part in the utilisation of iron by the body and that deficiency of vitamin C in the dietary may produce anaemia, is now well established. In the treatment of iron-deficiency anaemias, therefore, an optimal intake of vitamin C is important for effecting complete recovery.

It has been reported that certain cases of pernicious anaemia, resistant to liver therapy alone, have responded when vitamin C was added.

These facts point to the advisability of providing an ample intake of vitamin C in the treatment of anaemia generally.

Ribena Blackcurrant Syrup is not only a rich source of the vitamin (not less than 20 mg per fluid ounce), it also contains the associated factors of vitamin C in its natural form.

Mineral RE-ARMAMENT

Doctors agree that no mother must be permitted to draw on her own mineral deposits in bones and teeth to build the embryo—and many of them find that years of rationing increase this danger. Equally no child should be born with a frame deficient in minerals if ante natal care can prevent it. Calfos Natural Mineral Tablets provide the solution.

In easily assimilable form Calfos supplies calcium and phosphorus with all trace elements found in normal healthy bone. For every mother and child Calfos offers the essential daily intake of these minerals to remedy dietary deficiencies. Calfos builds sound bone and teeth and increases resistance to disease.

Each tablet contains 5 gr. of the natural mineral constituents of bone equivalent to 1.7 gr. calcium and 0.77 gr. phosphorus

UNIVERSITY OF LEEDS

A week end course in industrial medicine will be held on Saturday and Sunday, May 3 and 4, and the programme is as follows: May 3, 2.30 p.m., Dr A J Amor, 'The Clinical Approach to Industrial Medicine', 3.45 p.m., Prof G P Crowden, 'Fatigue in Industry', 5.30 p.m., Dr G R Hargreaves, 'Psychiatry in Industry', May 4, 10.30 a.m., Dr F F Hellier 'Industrial Dermatitis', 11.45 a.m., Dr J Vaughan Jones, 'Rehabilitation', 2.15 p.m., Dr C Sutherland, 'Respiratory Disease in Industry'. Full particulars and form of enrolment may be obtained from the senior administrative officer, the Medical School, Leeds, 2

UNIVERSITY OF MANCHESTER

The Council of the University has approved the promotion of Frederick Arthur Langley, MSc, MB, ChB, from Assistant Lecturer to Lecturer in Pathology, from September next

Ralph Arthur Bailey, MD, and Eugène Leeson Willis, FRCS, have been appointed Clinical Demonstrators in Anatomy

UNIVERSITY OF SHEFFIELD

The following appointments were made at a meeting of the University Council on Feb 21: Honorary Lecturer in Public Health: LI Roberts, MD, MRCP; Honorary Lecturer in Radiological Anatomy: J Wilkie, MB, ChB; Honorary Lecturer in Bacteriology: L G Cook, MB, ChB; Assistant Lecturer in Physiology: A A Glynn, MB, BS. The resignation of Dr D J Clark of the post of Honorary Lecturer in Public Health was received and Dr Clark was thanked for his services to the University

ROYAL COLLEGE OF SURGEONS OF ENGLAND

The following surgery lectures will be delivered at the College (Lincoln's Inn Fields WC) at 5 p.m. on each day: March 31, Sir Cecil Wakeley, Surgery of the Thyroid Gland, April 1 and 2, Prof James F Brailsford, Bone Tumours, April 9, Mr F A R Stammers, Surgery of the Posterior Fossa of the Skull, April 10, Mr Philip H Mitchiner, Gangrene (excluding Gas Gangrene), April 11, Mr H S Soutter, Surgical Treatment of the Oesophagus, April 14, Mr L R Broster, Surgery of the Suprarenal Gland, April 16, Prof R V Bradlaw, Tumours of the Jaws, April 17, Mr George F Siebbing, Radiotherapy in the Treatment of Cancer, April 21, Mr Rainsford Mowlem, Replacement of Skin Loss in Traumatic Injuries, April 23, Mr Julian Taylor, Surgery of the Anterior Cranial Fossa, April 24, Sir Lionel Whitby, Blood Transfusion. The fee for the whole course is £5 5s. Fellows and Members of the College and Licentiates in Dental Surgery will be admitted on payment of a fee of £3 3s. Applications accompanied by a cheque for £5 5s. or £3 3s., should be sent to the assistant secretary of the College

Medical Notes in Parliament

FREEDOM TO PRINT

In the House of Commons on Feb 25 Sir W SMITHERS asked the Prime Minister if, since the use of industrial electricity was to be resumed in some areas only, he would ensure that all weeklies and similar periodicals should be suppressed or allowed to go to publication without discrimination

Mr ATTLEE said that to avoid discrimination the restrictions on the publication of weekly and other publications imposed from Saturday, Feb 15, applied equally in all areas of Great Britain. Similarly, the removal of the restrictions, announced on Feb 21 to permit the resumption of publication on and after March 3, applied to all areas, irrespective of the resumption in the use of industrial electricity in any particular area

Sir W SMITHERS said 'Was the Prime Minister aware of a strong and widespread feeling that the suppression of these periodicals was for political ends?'

Mr ATTLEE: If the hon Member shares that impression he had better get rid of it, because the whole point is that it applies equally to all political opinions

Mr FRANK BYERS: 'By what statutory or other authority was this suppression made, and will the Prime Minister give a categorical assurance that there was a statutory authority?'

Mr ATTLEE: It was actually done by agreement—(Cries of 'Oh!')

Mr BYERS: In that case is it not a fact that those people who are not members of the PPA are not bound by the agreement which was reached?'

Mr ATTLEE: This was done by agreement

The point made by Mr Byers was raised again on Feb 26 when Mr SHINWELL said he had been asked whether there was any statutory provision for the action taken in the suppression, temporarily, of periodicals. The answer was that there was, of course, no statutory provision, but it was possible to gain the consent of those who represented for the most part the weekly periodicals

Mr BYERS: Sixty per cent

Mr SHINWELL said there was a majority. There was naturally some discontent about the decision, but the action had to be taken having regard to all the circumstances, and he thought the action taken by those responsible for conducting negotiations was, on the whole, satisfactory

Mr BYERS asked why the order said that publications "are not permitted"

Mr SHINWELL replied that he had to rely for the most part on voluntary co-operation (Laughter) but an instruction of some sort had to be given. The parties concerned naturally sought guidance, but the matter would be disposed of very shortly. Already an arrangement had been made for the resumption of those periodicals

Mr BYERS: In other words it was a bluff!

In the House of Lords on Feb 27 LORD WOLVERTON asked under what statutory powers the Government suspended publication of certain periodical journals. An extremely important point was that of discrimination. The Prime Minister had stated that the course was adopted by agreement—it was understood with the Periodical Press Association. Not all periodicals belonged to that association. The Minister of Fuel and Power had stated there was no statutory provision for the action taken. The manner in which the direction was issued was entirely unsatisfactory because it was regarded in many instances as an order. A very dangerous precedent had been established, and he hoped that nothing of the sort would occur again

The EARL OF INDESLEIGH asked if the legal position had been made perfectly clear to the proprietors of local weekly newspapers. There had been some loose and, no doubt quite inaccurate talk of a ban on retail periodicals. That was the wrong word to use in connexion with what was a purely patriotic compliance with the Government's wishes. A current story, which came originally from American sources was that an American firm had offered to print and finance in dollars the weekly *Economist* and to import it at no cost in dollars. Was there any truth in the statement that an import licence for such an edition of the *Economist* was refused and if so on what grounds?

LORD DE LISLE and DUDLEY said the unfettered liberty of the Press—subject to the laws of blasphemy, libel, and other necessary regulations—was one of the bulwarks of our freedom. Anything which curbed or indirectly threatened it must be jealously guarded against and investigated by Parliament. He did not regard even a fuel crisis as a necessary or good excuse

for the suppression of comment on public events and particularly when in many cases, it was intelligent comment.

The EARL of GAINSBOROUGH asked why *his* the Oxford undergraduate periodical, was included—although it was produced by hand.

LORD CHORLEY said the Government of this country had for many years past recognized the vital importance in a democratically governed country of the complete liberty of the Press, and the vital part played by the Press in moulding the opinion by which political work was guided in this country. It was in view of the gravity of the situation that action was taken to suspend publication of the periodicals for a short period. It was in no sense a censorship or attempt to gag the Press, but a necessary step in a grave crisis. It was quite impossible in the circumstances to get into touch with all the proprietors concerned. It was obviously known to those concerned that there was no statutory power under which the Government would or could suspend newspapers.

VISCOUNT SWINTON asked whether it was worth doing at all. The sentences imposed on the papers were longer than anybody, and certainly the papers supposed. The Minister of Fuel and Power said that this would be a matter of three or four days, but it had been going on for several weeks and still there was no end. When the Minister or his representatives gave these papers the advice or instruction, were they advised or instructed that this absence of light was to last for three or four days and was it upon this comforting assurance that a proportion of the papers agreed to suspend their activities? Both Houses of Parliament had been led to suppose that there was no legal power to order this suspension.

LORD AMMON said that there was no legal sanction but directions could be made against a firm under Defence Regulation 55. But as the ban was to be lifted on Monday next it would not be worth while to do so.

SCOTTISH HEALTH SERVICE BILL

The Standing Committee on Scottish Bills further considered the National Health Service (Scotland) Bill on Feb 11, 13, 18 and 20. Clauses 6-20 with only minor amendments were ordered to stand part of the Bill. Discussion of Clause 21 on the provision of services by local health authorities, and of Clauses 22 and 23 was completed on Feb 25. Unfortunately it was not possible to give any account of these proceedings in our 'Pemmican' issues of Feb 22 and March 1.

When the Committee met on Feb 27 it was agreed that during the further consideration of the Bill the Committee should sit three days a week. Clause 24 was approved and Clause 25 was ordered to stand part of the Bill.

On Clause 26 Mr BUCHANAN said that compulsory vaccination in Scotland had to a large extent died down and the signing of objectors' declarations had become a commonplace. The position was that while the Bill abolished compulsory vaccination all reasonable arrangements would be allowed to the medical profession for them to vaccinate. The Clause was ordered to stand part of the Bill.

A drafting amendment was made on Clause 27, and Mr REID asked for information about the responsibility of local authorities. He asked whether it was intended that a lunatic should go to a State institution but a mental deficient to a local authority institution.

Mr BUCHANAN said it was not the intention of the Scottish Office to work this Clause when the Bill first came into operation. He was told that mental deficiency did include lunacy but he would look into the declaration again. In many matters the Scottish Office wished to see work done by particular authorities and not imposed on the whole of Scotland. The Clause as amended was ordered to stand part of the Bill as was Clause 28.

Mr REID asked whether Clause 29 was wide enough to ensure that there could be different appointed days for different parts of the same subsection. Mr BUCHANAN said that Clauses 20 and 21 would operate from the passing of the Bill but the other Clauses would operate from the appointed day, April 1, 1948. It was left to the discretion of the Secretary of State to decide when and how Clause 27 should operate. Under that Clause the Secretary of State had power to fix the appointed day. Clause 29 was then ordered to stand part of the Bill as was Clause 30 on executive councils. Clause 31 which sets up local representative committees, was also ordered to stand part of the Bill.

On Clause 32 which imposes on each executive council the duty of making arrangements with medical practitioners for the provision of personal medical services Mr REID moved to omit the words "whether at a health centre or otherwise." He said this was one of the most important clauses because it laid down the conditions under which the whole of the medical practitioner service of the country was to be employed.

Mr HASTINGS saw no reason for these words to be left out. They had been inserted in the English measure so that there would be no ambiguity.

Mr BUCHANAN said that when he consulted the drafting experts they did not know how the words ever got into the Bill. He was prepared to drop them as they possibly made things more ambiguous. Mr Reid's amendment was accepted.

Remuneration of Doctors

Mr REID then moved to insert a proviso that arrangements made under the Clause shall provide for remuneration in every case by capitation fees and might provide for additional remuneration by salary in any case where the executive council was satisfied that, owing to sparseness of population or other local circumstances, capitation fees would not provide adequate remuneration. He said that so far as he could find nothing in the Bill instructed the Government on the method of remuneration of general practitioners. At the last General Election the Labour Party policy was to have a full time salaried medical service. Mr Bevan speaking on the English Bill, was at pains to maintain that policy as an ultimate objective. Mr Reid did not know whether Mr Buchanan agreed with all that had been said by his English colleagues.

Mr BUCHANAN said that on the broad principles he accepted the Labour policy.

Mr REID argued that it was a fallacy to say that because it may be right to have a quarter of the medical profession on a salaried basis it was right to have them all on that basis. In view of the Labour Party policy the Committee must take it that the aim was that a salary should be a large part of the doctor's remuneration. He did not see how that helped the young doctor unless it was said that for the first five years a man was in practice he should get a basic salary. Mr Reid would not object to that but said the Committee could not say that Scotland was under-doctored and also that it would be extremely difficult for a young man to establish himself. He hoped that at the relevant time Mr Buchanan would assure the Committee that although assistants were hardly mentioned in the Bill they would be worked into the scheme. At what level and for what number of patients would the Government start to pay a basic salary? It was time that the medical profession was given some information. It was likely that Scotland would be able for some time to have a larger number of doctors per thousand than in England.

Mr BUCHANAN said that a basic salary was an essential element of the scheme although there might be one or two isolated cases where one could depart from it. There ought to be provision for the young doctor. During the war years no one had been poorer paid or worse treated than doctors' assistants. His nephew, who began with a Glasgow doctor found that he was getting about 6½d an hour and was packed off to all the maternity cases at night. Medical practice must be open to men on the grounds of their ability and not according to how well their pockets were filled. In 1942 the British Medical Association made a draft proposal which contained the element of basic salary. Medical Practices Committees made up of doctors alone decided where there was need for a doctor and he could then go in and start. That did not mean that he would get enough to live on. A basic salary plus capitation fee would enable a doctor without means to make his start. The basic salary should be used to attract the best kind of doctor to the poorer localities.

Mr MCKIE said the fear and anxiety of medical practitioners in the rural areas of Scotland under this Clause was legitimate and justifiable and Mr Reid's amendment sought to place them in a position to carry on their work in the future.

The proposed amendment was defeated by 21 to 11 and the Committee adjourned.

Control of Penicillin

Sir JOHN MELLOR on Feb 25 said that under Order No 731 of 1946 anyone who asked a chemist to sell him penicillin was guilty of a criminal offence unless he tendered a medical prescription. There was no longer any shortage of penicillin and the order was now quite unjustified. As he understood medical opinion in relation to penicillin that substance was in no way harmful but doctors considered that the reaction of the body to it tended to diminish with frequent use. Continuous use of many drugs would be undesirable but their sale was not limited by legislation. Under the Poisons Act and the Dangerous Drug Acts the Home Secretary had power to make regulations restricting distribution but he was not aware that any legislation had been passed to restrict the sale of therapeutic substances which were not harmful.

Mr JOHN LEWIS said the House should bear in mind that this drug could only be used with effect by injection. At

person who proposed to use it without a medical certificate had to give himself injections. No medical man would be happy if he knew that a patient without instructions and advice was injecting himself with whatever amount of penicillin he thought fit. In any case this valuable drug should not be wasted. He suggested that the Minister of Health should find out whether penicillin tablets of 500 units each, which could be bought in any chemist's shop without a doctor's certificate, were of any use. Wing-Commander ROLAND ROBINSON wished to know if the Government was seeking to narrow the use of penicillin in Britain so that it could be exported in competition with America.

Dr SANTO JEGER said the supply of penicillin should be controlled because when a new drug was discovered the public got the idea that it was a cure-all. There had been correspondence recently in the medical Press on deleterious effects following the use of penicillin lozenges.

Mr LEONARD replying for the Ministry of Supply said there was no serious risk that penicillin supplies would be insufficient to meet the requirements in this country of medical, dental, and veterinary practitioners. America had started with control and that control was lifted. Because of what happened afterwards it had been deemed in the national interest to reimpose it. Mr BEVAN had been advised by medical experts and also by Sir Alexander Fleming that there would be danger in the uncontrolled use of penicillin and that this should not be permitted. He was advised that there was a danger to patients and others by the creation of a strain of organisms resistant to penicillin treatment. A draft Bill had been prepared to control the sale and supply of penicillin otherwise than by Order.

Refugee Doctors

On Feb 20 Dr SANTO JEGER asked the Minister of Health whether in view of the fact that a larger number of doctors than at present available was necessary to implement his new National Medical Service next year and, in view of the fact that the Central Medical War Committee passed a resolution on this subject, he could state his policy on the admission of refugee doctors with foreign qualifications to practise in this country.

Mr BEVAN said the views of the Central Medical War Committee on this matter were sought by the Home Office acting in consultation with his Department. The Committee was consulting certain other professional bodies before communicating its views to the Home Office. (See Supplement Feb 8 p 25)

Streptomycin—Dr STEPHEN TAYLOR asked on Feb 18 whether Mr BEVAN would inform the medical profession of the hospitals at which the Medical Research Council tests of streptomycin were carried out so that they could send patients. Mr BEVAN replied that appropriate hospitals and clinics in the areas in which the tuberculosis trial centres were situated had been informed. The particulars would be circulated more widely if it was found advisable to draw upon larger areas for the limited number of cases of suitable type with which it was possible to deal.

Penicillin—At the request of Mr BEVAN, Mr Wilmot is retaining the Control of Penicillin Orders till other arrangements can be made. During January 1947, 225,387 mega units of penicillin were produced in the United Kingdom. The amount produced in this country is steadily increasing and is sufficient to meet all prescriptions and leave a small surplus for export.

Smallpox—Mr CREECH JONES stated on Feb 26 that the incidence of smallpox in Hong Kong had given rise to anxiety but the epidemic showed signs of abating. Proved cases in 1946 numbered 1,998 with 1,306 deaths. Between Dec 27 and Feb 6 there were 266 cases.

Typhus—No further cases of typhus have been reported on HMT *Empire Deben* since her return to this country with four such cases.

The National Society for the Prevention of Blindness announces that as papers submitted for the glaucoma prize of \$500 offered in 1944 did not conform to the criteria set up by the ophthalmological committee selected to award the prize it is again offered for the most valuable original paper adding to existing knowledge of the diagnosis of early glaucoma or the medical treatment of non-consecutive glaucoma. Papers may be presented by any practising ophthalmologist of the Western Hemisphere and may be written in English, French, German, Italian, Spanish or Portuguese. Those written in any of the last four languages should be accompanied by a summary in English. Closing date for receipt of papers is December 1947. The criteria may be secured by writing to the National Society for the Prevention of Blindness, 1790, Broadway, New York 19, New York, U.S.A.

The Services

Lieut Gen Sir Alexander Hood, Director General of the Army Medical Services, has been elected chairman of governors of the Star and Garter Home for Disabled Sailors, Soldiers and Airmen, Richmond, in place of Sir Arthur Stanley, who has resigned because of ill health.

Capt (Hon Major) D A Brigg, Capt (Hon Capt) S Lask and Lieut (Hon Capt) G Bennett, R.A.M.C., T.A., have been awarded the Efficiency Medal (Territorial).

Capt (Hon Major) W R Blunt, R.A.M.C., has been awarded the Efficiency Medal (Territorial).

CARDIFF MEDICAL EX-SERVICE ASSOCIATION

The first annual dinner of the Cardiff Medical Ex-Service Association will be held at Park Hotel on Saturday, March 15, at 7 p.m. for 7.45 p.m. The dinner is primarily for medical men who are old students or members of the staff, past and present, of the Cardiff Medical School, who have served in either Great War. Guests may be invited provided they are ex-Service medical men. Tickets (12s 6d each, exclusive of wines) may be obtained from the secretary, Mr K M Wheeler, Surgical Unit, Royal Infirmary, Cardiff.

Medical News

The annual general meeting of the Society of Public Analysts and other Analytical Chemists will be held at the Royal Society's rooms (Burlington House, Piccadilly, W.) on Friday, March 7, at 3.30 p.m., and will be followed, at 4 p.m., by an address by the retiring president, Dr G W Monier-Williams.

A meeting of the Microbiological Panel of the Food Group of the Society of Chemical Industry will be held at the Chemical Society's rooms (Burlington House, Piccadilly, W.) on Wednesday, March 12, at 6.30 p.m., when papers will be presented on 'The Biological Stability of Beer,' by Mr B M Brown, and 'The Biological Stability of Cider, Fruit Juices, and Soft Drinks,' by Prof B T P Barker and Dr V L S Charley.

The annual general meeting of the Institute of Almoners will be held at Friends House, Euston Road, London, N.W., on Friday, March 14, at 6 p.m., when Dr J A Charles will deliver an address.

The annual dinner of the Midland Branch of the Society of Medical Officers of Health will be held at the Whitehouse Hotel, Congreve Street, Birmingham on Tuesday, March 18.

A meeting of the Food Group of the Society of Chemical Industry, to which all members of the Agriculture Group are invited will be held at the Royal Institution (Albemarle Street, W.) on Wednesday, March 19, at 6.30 p.m., when Dr W G Ogg will present a survey of the work of the Rothamsted Experimental Station.

The first convention of the Society of Chiropractors (21, Cavendish Square, London, W.1) will be held at Friends House, Euston Road, London, N.W., on Thursday, Friday and Saturday, March 20, 21, and 22. The convention will be opened on March 20 at 2.30 p.m., by Sir Hugh Lett, President of the British Medical Association, at 3 p.m. Prof A B Appleton will deliver a lecture on 'Posture', and at 7.15 p.m. the annual dinner (tickets £1 10s) will be held at the Savoy Hotel. On March 21 lectures will be delivered by Mr Philip Wiles on 'Pain and Deformity of the Metatarsals and Toes' at 10 a.m. by Mr Denis Browne on 'Minor and Major Deformities of the Feet in Children' at 11.30 a.m. and by Prof A J E Cave on 'The Foot as a Sensory Organ' at 6 p.m. On March 22 at 10.30 a.m., the annual general meeting of the society will be held and at 3 p.m. Dr Allan Yorke will lecture on 'Hyperkeratosis of the Sole of the Foot'. The convention fee is 10s 6d for members and 5s for students at any of the schools of chiropraxy recognized by the Board of Registration of Medical Auxiliaries. During the convention there will be an exhibition and visits may be paid to the three schools of chiropraxy in London.

The second International Congress of the International Academy of Legal and Social Medicine will be held at Brussels and Liège from June 25 to 28 and will be divided into five sections: legal medicine in its application to crime, social medicine, industrial medicine, medico-legal and social psychiatry and scientific police methods. The languages will be English and French. Those who wish to present reports or read papers should notify without delay the president of the Congress Prof Dr M De laet, Faculté de Médecine, 7 Rue de la Gendarmerie, Brussels or one of the general secretaries Prof Dr P Moureau (47, Rue Villette, Liège) or Prof Dr F Thomas (23, Kluyskensstraat, Ghent).

Sir Harold Hartley, delivering an address on "A Century of Chemistry" at a joint meeting of the Royal Society of Arts and the Chemical Society at the Royal Society of Arts on Feb 19, with Sir Thomas Holland presiding, said that they were commemorating the first meeting of the Chemical Society, which took place there in 1841. The Society had been founded just over half a century after Lavoisier had laid down the first clear distinction between physical and chemical change. Dalton's atomic theory soon followed, and made possible the work of Berzelius determining the atomic weight of every known element and the composition of many compounds. Liebig, Wohler and Dumas had been laying the foundations of organic chemistry by making series of derivatives from natural products. By 1841 the authority of Berzelius had been seriously challenged, and when the Chemical Society had been founded there was a drift from theory towards empiricism. Kekulé's theory of atom linkage had enabled him to assign definite structures to organic compounds, and in 1860 Cannizzaro's treatise had led to general agreement on atomic weights and the number of atoms in a molecule. In 1860 only 60 elements had been known. The development of the periodic table by Newlands, Lothar Meyer, and Mendeleeff had enabled prediction of the properties of unknown elements, which were discovered with the help of the spectroscope. The outstanding work in organic chemistry since 1900 had been on the materials and processes of living organisms. X rays were of decisive help in elucidating the structure of the main constituents of living organisms—the polysaccharides and the proteins—and work on the structure of proteins was beginning to reveal the processes of growth. Our knowledge of the enzymes, vitamins, hormones, and auxins had advanced rapidly and the identification of the vitamins had been of profound importance in nutrition. The isolation and in some cases the synthesis of the hormones had been of great value in curative medicine.

The third Annual Convention of the American Society for the Study of Sterility will be held at Hotel Strand, Atlantic City, New Jersey, on June 7 and 8. There will be lectures, discussions, and demonstrations with the object of bringing to the medical practitioner recent advances in this field. Further information may be obtained from Dr John O Haman, 490, Post Street, San Francisco, 2 California, U.S.A.

The King has sent an annual subscription of £1,000 for 1947 to King Edward's Hospital Fund for London.

As the result of improved methods of mass production the Commonwealth Serum Laboratories at Melbourne, Australia, are producing 50 times as much penicillin as in December, 1943. The supply is now sufficient for Australia's own needs. The retail selling price is about 3s 5d for 100,000 units.

Food and Nutrition is a magazine issued every fourth week from the Ministry of Food and published by H.M. Stationery Office, price 3d. The January issue contains articles on ten ways of cooking sausages, the nutrients in milk, with an observation on milk collection, distribution, and consumption, the latest "points" value news, and a note on the growing of bananas in Iceland.

Penicillin is available in two forms, the ordinary yellow penicillin, and "white" penicillin, which may be crystalline or amorphous. The Ministry of Health has asked pharmacists to note that when dispensing N.H.I. prescriptions for extemporaneously prepared topical preparations the ordinary yellow penicillin or solution tablets should be used. "White" penicillin should be reserved for the preparation of injections and eye drops. The pricing of prescriptions dispensed during February will be done on this basis.

Dr H. P. Chu, dean of the National Medical College at Shanghai and formerly secretary of the Chinese Medical Association, has arrived on a three months' visit to this country arranged by the British Council. This is the first time he has visited Britain. He is studying undergraduate and postgraduate medical education, the curricula of British medical schools, and all forms of medical teaching, including the training of nurses. Arrangements have been made for him to have discussions with the appropriate authorities and to visit teaching hospitals and other institutions in London and the provinces.

The Secretary of State for Scotland has appointed Mr G. H. Kimpton to be an Under Secretary in the Department of Health for Scotland. He will be in charge of the Divisions of that Department which deal with health services in Scotland. Mr Kimpton joined the Department in 1913 and has had wide experience of health and housing matters. He was promoted to the rank of Principal in 1935 and became an Assistant Secretary in 1940. He served as a member of the Inter-departmental Committee on the Rents Restriction Acts.

Dr T. S. Marshall has been appointed Regional Blood Transfusion Officer in charge of the Regional Transfusion Centre temporarily housed at Meanwood Park Colony, Tongue Lane, Leeds. The centre, which is responsible for the transfusion needs of the Leeds Regional Hospital Area, will move later this year to premises at Seacroft Hospital, Leeds.

EPIDEMIOLOGICAL NOTES

Smallpox at Grimsby

In the outbreak of smallpox at Grimsby infection originated in a common lodging house between Jan 31 and Feb 2, but the source remains unidentified. The second generation of cases involved two elderly inmates of the common lodging-house who sickened on Feb 13 and 14 and have since died. The disease was first detected on Feb 17.

Between Feb 27 and March 3 there have been 10 cases diagnosed in the third generation and two of these patients have died, one of them before the appearance of a focal rash. All were in the direct line of contact with second generation cases and were under surveillance in Grimsby at the time of onset. Ten contacts at the common lodging-house remain untraced and there is no information about their movements. They are believed to include mariners, either aboard trawlers and coastal vessels or visiting Scandinavian ports, and also migrant Irish agricultural labourers. The present uncertainty calls for the greatest vigilance on the part of practitioners.

Typhoid at Watford

Three cases of typhoid have occurred in one family in the Watford area. The first case was notified on Wednesday, Feb 5, and no further notifications have been received since then. Investigations have shown that the mother is a carrier and the usual precautionary measures have been taken.

Influenza and Measles

Influenza apparently reached its maximum incidence in the week ending Feb 8. In the 126 great towns 646 deaths were attributed to influenza during the first six weeks of this year. This should be compared with 1,337 in the same period last year.

The epidemic curve of measles is reaching a maximum, although a further rise during the next few weeks is probable judging from past experience. The notifications during the weeks preceding the peak in the present epidemic so far have been below the level of the last two outbreaks of 1943 and 1945.

Discussion of Tables

In England and Wales a decreased incidence was recorded during the fortnight for scarlet fever 156, whooping cough 309 and dysentery 48. A rise in both weeks in the notifications of measles gave a total increase of 5,587 cases. A decrease of 71 in the notifications of diphtheria in the week ending Feb 1 was offset by an increase of 57 in the following week.

The decrease in the incidence of scarlet fever was general throughout the country, while the fall in cases of whooping-cough was greatest in the north.

The returns for diphtheria for the week ending Feb 1 were the lowest ever recorded, being 4 below the previous record low level at the end of December. The notifications of diphtheria for the first few weeks of this year are less than half of those recorded in the same period of last year and only one sixth of the average of the first weeks of 1937-9.

In Scotland the weekly fluctuations in the notifications of infectious diseases tended to cancel each other out during the fortnight. The only diseases showing a continuous trend were acute primary pneumonia with a total increase of 82 cases and cerebrospinal fever with a total decrease of 11. The incidence of dysentery, with a decrease of 22 followed by a rise of 16, was mainly affected by the experience of Edinburgh where the cases fell from 16 to 1 and then rose to 13.

In Eire the increased incidence of measles was due to two outbreaks. Cork Castle town R.D. 26 cases and Mayo, Belmullet R.D. 17 cases. In the first week of the fortnight the notifications of whooping cough in Dublin, C.B. fell from 78 to 43. The rise in the incidence of scarlet fever was due to a small general increase. Notifications of diarrhoea and enteritis during the week ending Feb 1 (12 cases) were the lowest for twelve months.

In Northern Ireland the epidemic of measles in Belfast C.B. has passed its maximum. 1,499 cases were notified in the fortnight compared with 1,799 in the preceding two weeks. (See also Feb 15, p. 280.)

Week Ending February 22

The notifications of infectious diseases in England and Wales during the week included scarlet fever 1,081, whooping cough 2,227, diphtheria 217, measles 15,765, acute pneumonia 1,139, cerebrospinal fever 90, acute poliomyelitis 14, dysentery 92, smallpox 2, typhoid 3. Deaths from influenza in the 126 great towns numbered 135.

INFECTIOUS DISEASES AND VITAL STATISTICS

No 5

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Feb 1

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland
Figures of Births and Deaths recorded under each infectious disease are for (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland
A dash — denotes no cases a blank space denotes disease not notifiable or no return available

Disease	1947					1946 (Corresponding Week)

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Sulphonamide Snuff for Colds

Q—*Could frequent snuffing of sulphapyridine powder as a preventive of colds cause damage to the blood similar to that resulting from prolonged overdosage by mouth?*

A—It is difficult to believe that anyone would take sulphapyridine snuff every two or three hours daily throughout a winter and even if he did he would be lucky to escape colds. Assuming, however, that this is what is meant, the answer is that in a small minority of individuals a toxic effect on the bone marrow might be produced. This has been the experience when sulphanilamide or sulphadiazine has been given in small doses for long periods with a view to preventing recurrences of rheumatic fever. Sulphapyridine is very insoluble. Taken as snuff most of it would be carried to the pharynx in mucus and swallowed, still in solid form, with the same result as if it had been taken by mouth. A more suitable sulphonamide for use as snuff, when this treatment is really indicated is sulphathiazole. It is very doubtful whether sulphonamide snuffs are of any value except for the treatment of certain specific bacterial infections or carrier states.

Pseudo-Hermaphrodite

Q—*A healthy woman aged 35 recently gave birth to a 9½-lb (4.3-kg) baby. Presuming the baby to be a girl the labia majora are wide with a small rounded swelling in the centre of each giving the appearance of a scrotum divided in two down the middle and are separated by a mucous membrane. The clitoris is slightly enlarged and the labia minora are absent. The vagina is represented by a shallow dimple and the umbilicus is immediately above the symphysis pubis. Is there any test to determine the sex, and is hormone treatment of use?*

A—It seems likely that the small rounded swellings in the labia are gonads, and, if this is so, they are probably testes, the "labia majora" being in fact a bifid scrotum and the enlarged clitoris a rudimentary penis. This type of abnormality of the external genitalia is by no means uncommon. The lower abdominal wall is not so often involved, but this feature of the case is not surprising bearing in mind that the external genitalia are developed in the area of the ectodermal cloaca, which extends initially from the body stalk to the rudimentary tail.

It will be difficult to prove the child's sex by chemical or other clinical tests. Estimation of the excretion of the 17-ketosteroids in the urine might be of some value. Thus if the child were female the virilism (for example, the enlarged clitoris) will probably be the result of overactivity of the adrenal cortex and the ketosteroid excretion would be high. On the other hand, if it is a male, the 17-ketosteroid excretion is likely to be as in normal male babies—at an extremely low level. However, too much reliance could not be placed on tests of this kind because the normal excretion levels of the various hormones and their end-products have not yet been established for infancy and childhood. It will almost certainly be necessary to determine the sex by biopsy of the gonad, and at the same time it will be desirable and important to carry out laparotomy to see what internal genital organs are present. One of the difficulties is to decide the time at which surgical intervention should be carried out. Every case has to be judged on its merits but the general view is that operation should be deferred until after puberty—that is until such time as there is evidence as to the nature of the secondary sex characters including the mental outlook and sex impulses. In addition to determining the true state of affairs by laparotomy it will then be possible at the same time to carry out some sort of sex-formative operation, and in doing so the wishes of the individual should be kept in mind. Thus, if the natural inclinations are feminine the testes in the labia and the phallus could be removed.

If it is decided to adopt this waiting policy the child should in the meantime be brought up as a male. Nearly all these cases turn out ultimately to be male, and in any case there is less risk of social difficulties if a female pseudo hermaphrodite is sent to a boys' school than if a male pseudo hermaphrodite is sent to a girls' school. The later developments in cases of this kind are varied and difficult to foretell even if the nature of the gonad is known. Secondary sex characters, including sex desire, depend so much on the other endocrine organs and the ultimate outlook of the individual may be feminine or masculine. It is unlikely that hormone therapy will be of practical value in any attempt to alter the sex at a later age, the better plan will be to aim at modifying by plastic surgery the genital apparatus to suit the individual rather than vice versa.

A Child in Moral Danger

Q—*I was called to see an 11-year-old girl with bronchitis. Her mother confided to me that her husband, recently returned after an absence of six years, had been behaving very strangely towards the girl. He takes her out each evening and the neighbours are beginning to talk. The mother coming suddenly into the house has often found them in compromising positions. On one occasion she found her husband embracing the girl with his hands on her breasts which are fairly well developed. The maternal grandmother has seen many similar incidents once she saw them separating from an embrace and the girl was flushed and panning and looked frustrated. The husband was untouched by an appeal from his wife pointing out the impropriety of his conduct. What do you advise?*

A—Under Section 61 of the Children and Young Persons Act, 1933 if a juvenile court is satisfied that a child is in need of care or protection it has various powers, including the power to remove the child from home or to place it under supervision. A child in need of care or protection is among other things, one whose parent or parents are not looking after it properly and who is in moral danger. If evidence could be adduced that a father is interfering sexually with his child even though such interference did not merit a criminal charge of incest, the child would almost certainly be deemed to be in need of care or protection. Proceedings under this section can be initiated, *inter alia*, by the police or by an authorized person. In practice the only "authorized person" is the NSPCC.

In the present case the doctor (or, indeed, anyone else in whom the mother had confided) should in the first instance explain the legal position to the mother as set out above. It is then for her to decide, preferably in consultation with the police or the NSPCC (she would probably prefer the latter) whether the evidence is strong enough to bring a case, it being borne in mind that both the father and the girl will probably vehemently deny all the allegations made. If, however, the mother's observations can be confirmed in court by those of the grandmother there would seem to be some chance of a case under this section being successful. On the other hand if it is felt that the evidence is not sufficient, then the mother and grandmother can do no more than continue to keep watch. It may well be, of course, that the threat of proceedings will deter the father from making any further advances—at least for the time being. In considering what action to take, the mother will naturally have regard to the effect of such proceedings, or the threat of them, upon her marriage. If, as the result her husband leaves her, she would then be free to apply to the court for a maintenance order giving her the custody of the child.

The address of the headquarters of the NSPCC is Victoria House, Leicester Square, London, WC2.

Bleeding Tooth-sockets

Q—*Apart from mechanical means what specific remedies can be applied for a bleeding tooth socket following dental extraction?*

A—Mechanical methods offer much the best hope of stopping haemorrhage from a tooth socket, but these methods may be combined with the local use of drugs. Snake venom or pectin derivatives can be used locally and general agents such as calcium may be injected. Mechanical means are usually sufficient by themselves. It is important, however, that the

plug should not be pushed into the tooth socket but only placed over it as prevention of the normal clot forming in the socket inevitably leads to sepsis sequestration of the bony walls and delayed healing

Cooking Eggs and Salmonella

Q—You published (Oct 19 1946 p 583) an annotation about the danger of infection of dried egg powder by salmonella organisms. Is there any method of cooking which will neutralize this danger?

A—Salmonella organisms have the usual susceptibility of non sporogenous bacteria to heat, that is to say, at 55°C they are killed within 30 minutes and at higher temperatures in proportionally shorter periods survival at over 70°C being measured in seconds rather than in minutes. The following culinary methods of using egg or egg powder must be considered in this light. In the preparation of salad creams no heat is employed, the organisms survive unless killed by vinegar. When poaching eggs (this applies only to shell eggs) the yolk is not adequately heated and the organisms survive, this is the commonest mode of infection. The same applies to light boiling. In scrambling and omelette making, if the whole of the mixture is coagulated the organisms will be killed if any of it remains fluid they may not. Only cake-making may be considered entirely safe.

Dermatomyositis

Q—A boy of 16 is suffering from dermatomyositis. What are the aetiology and the prognosis of this condition and is there any possibility of cure?

A—The aetiology is unknown, some believe the affection to be infective others that it has an endocrine origin—especially related to dysthyroidism. Prognosis is very variable recovery may occur or the affection may remain stationary at a stage not causing great disability. Death is often by intercurrent respiratory disease if disablement involves the chest musculature. Biochemical investigation may help to indicate a method of treatment, especially in relation to sodium and potassium metabolism. A similarity to myasthenia gravis and to Addison's disease should not be overlooked. Occasionally epinephrine has seemed to help. Treatment is essentially symptomatic.

Itching of the Hands

Q—A lady aged 40 complains of intolerable itching of the hands soon after immersion in cold water. With warm water the irritation is not so marked. Examination reveals no abnormality of the skin the local temperature being unaffected. She is subject to Raynaud's phenomenon and moderate chilblains on the fingers in the winter. Any advice would be appreciated.

A—It would be interesting to know how long the patient has been subject to this trouble and whether it followed any infective illness. The condition would seem to be related to cold urticaria which is generally seen at puberty or after an infective illness. This is apparently due to the local effects on the smaller vessels and nerve-endings of a metabolite produced in the tissues by the cold. Benadryl might control such a reaction. Vitamin K therapy might improve the poor peripheral circulation and reduce the tendency to such reaction.

Third-generation Syphilis

Q—Is congenital syphilis a cause of sterility or infertility? If not is it possible for a congenital syphilitic to transmit the infection to his or her offspring?

A—Congenital syphilis is no more likely to cause sterility or infertility than the acquired form or than any disease which affects the organs of procreation. Naturally such conditions as congenital tabes or GPI are likely to cause infertility and gummas of the testicles to result in sterility. Such conditions are rare. It is generally believed nowadays though it is denied by some that third generation syphilis does occur but it is certainly very rare. It does not seem possible for a congenitally syphilitic male to produce a syphilitic baby by a healthy mother.

Letters and Notes

Photographs of Nigerian Pagans

An exhibition of photographs, taken by Dr Joseph Denfield was opened on Monday, Feb 10, by Mr Michael Huxley, Editor of the *Geographical Magazine* at the Ilford Galleries, 101, High Holborn, London, WC1. These photographs were taken by Dr Denfield during his tour of military service in Northern Nigeria. They illustrate vividly the life of the pagan inhabitants of the Bauchi Plateau who live in conditions almost entirely unaffected by Western civilization. Apart from their very high artistic merit many photographs bring out points of medical interest: the use of keloids for personal adornment, the decorative value of nose and lip plugs, duck-billed women, a fashion originally introduced to make females unattractive to raiders from other tribes but persisting even when raiding has ceased. A tight string round the neck is said to be a sovereign remedy against endemic goitre, which has a high incidence in some of the villages.

The Igwe tribe is divided into male and female sections: a male of the female section is forbidden to wear any clothes whatsoever, while his hair must be dressed in feminine style. Psychoanalysts have not yet visited this tribe. One photograph illustrates the flogging ceremony of the Fulani. It may seem a little odd to select your herdsman because of his power to endure a severe flogging without flinching, but like the Spartans in ancient Greece no Fulani youth even to-day has any chance of obtaining a wife unless he has proved his manhood in this way. The exhibition will remain open for some weeks.

Control of Measles

Mr ELWIN HARRIS FRCS (Bristol) writes: I am interested in the articles on measles in the *Journal* for Feb 8 (pp 209 and 225). Many years ago oiling the patient was recommended for scarlet fever, and I have always used it in the treatment of measles. The treatment consists of a hot blanket bath followed by the application of oil to the whole body. The oil used is of eucalypti 10 min (0.6 ml) and of olive oil 1 oz (28 ml). This is carried out each evening and in severe cases in the morning as well. I cannot recall a single case of oil in media complicating measles during twenty-two years of general practice. I have attributed the efficacy of the treatment to the fact that the patient inhales the eucalyptus through out the night, but your articles suggest that it may be otherwise. Not only is the treatment effective in preventing complications, but it is extremely soothing to the patient and induces sleep. Oiling floors and sheets is hardly practicable in domiciliary practice, but oiling the patient is easy and, in my experience, extremely effective.

Correction Whooping-cough Immunization

In the answer to the question (Feb 1 p 207) as to which public health authorities were carrying out immunization against whooping cough on a large scale it was stated that trials had been organized in the boroughs of Tottenham and Wembley and in the City of Manchester using American vaccines. A somewhat similar trial using Sauer vaccine was undertaken in Oxford in 1944 with the co-operation of the medical officer of health and the Medical Research Council. This Oxford trial should have been mentioned in the original answer.

—Correction

In the *Journal* of Feb 8 at page 224 under "Books Received" the editors of the book *The Nation's Food* were incorrectly designated the following is correct: A L Bacharach, M.A., FRIC and T Rendle, FRIC, with an introduction by Sir Joseph Barcroft CBE, FRS.

In the reply to a question on the increase in tuberculosis (Jan 4 p 39) the figures for tuberculosis from 1939 to 1944 were those for males only.

NEGOTIATING COMMITTEE

The Negotiating Committee met Mr Aneurin Bevan, the Minister of Health on Friday, Feb 28. The representations made to the Minister were based on the following resolution passed at the Special Representative Meeting of the Association on Jan 28, and subsequently adopted by the Negotiating Committee

"That the Association, having considered the final results of the plebiscite and the Minister's letter of Jan 6 to the Presidents of the Royal Colleges and desiring to secure for the people the best possible health service, is willing that discussions be entered into with the Minister to that end, provided that such discussions are comprehensive in their scope, and that the possibility that they may lead to further legislation is not excluded and that after the conclusion of these discussions, a second plebiscite be taken on the issue of entering the Service"

- As an outcome of the meeting, six subcommittees of the Negotiating Committee dealing with general practice hospital and specialist services, public health mental health services, eye services and superannuation, respectively will begin comprehensive discussions with the Ministry based on the resolution of the Representative Body

Association Notices

SCHOLARSHIPS IN AID OF SCIENTIFIC RESEARCH

The Council of the British Medical Association is prepared to receive applications for Research Scholarships as follows: an Ernest Hart Memorial Scholarship of the value of £200, a Walter Dixon Scholarship of the value of £200, and four Research Scholarships, each of the value of £150. These Scholarships are given to candidates whom the Science Committee of the Association recommends as qualified to undertake research in any subject (including State Medicine) relating to the causation, prevention or treatment of disease. Preference will be given, other things being equal to members of the medical profession. Each scholarship is tenable for one year, starting on Oct 1. A scholar may be reappointed for not more than two additional terms. A scholar is not necessarily required to devote the whole of his or her time to the work of the research but may hold a junior appointment at a university, medical school, or hospital, provided the duties of such appointments do not interfere with his or her work as a scholar.

Conditions of Award Applications

Applications for scholarships must be made not later than Saturday, May 31, on the prescribed form, a copy of which will be supplied on application to the Secretary of the Association, BMA House, Tavistock Square, London WC1. Applicants are required to furnish the names of three referees who are competent to speak as to their capacity for the research contemplated.

Branch and Division Meetings to be Held

NORTH OF ENGLAND BRANCH—At Royal Victoria Infirmary, Newcastle-upon-Tyne, Thursday, March 13, 7.15 p.m. Clinical demonstration by Mr J. V. Todd. Treatment of Common Foot Disorders, 8.45 p.m., Surg. Rear-Admiral R. J. Willan. Forty Years Experience of Haematuria in Surgical Practice.

RICHMOND DIVISION—At Royal Hospital Richmond, Friday, March 14, 9 p.m. Dr R. M. B. MacKenna. Modern Trends in Dermatology.

WAKEFIELD, PONTEFRAC T AND CASTLEFORD DIVISION—At Clayton Hospital Wakefield, Thursday, March 13, 8.15 p.m. Prof R. E. Tunbridge. Peripheral Vascular Disorders.

DIARY OF SOCIETIES AND LECTURES

ROYAL COLLEGE OF SURGEONS OF ENGLAND Lincoln's Inn Fields, WC—*Mon* 3.45 p.m. Dr L. E. Glynn. Aneurysms and Aneurysm Formation. 5 p.m., Prof E. Goldby. Intra Cranial Anatomy of the Trigeminal Nerve. *Tues* 3.45 p.m. Prof P. R. Peacock. Aetiology of Gastric Cancer. An Experimental Approach. 5 p.m., Prof E. Goldby. The Anatomy of the Optic Pathways. *Wed* 3.45 p.m., Prof A. Haddow. Cancer as a Problem in the Transformation of Cells and Viruses (1) Carcinogenesis by Chemical Agents. 5 p.m., Prof C. M. West. The Reproductive System (1). *Thurs* 3.45 p.m. Prof A. Haddow. Cancer as a Problem in the Transformation of Cells and Viruses (2). The Nature and Role of Tumour producing Viruses. 5 p.m., Prof C. M. West. The Reproductive System (2). *Fri* 3.45 p.m., Dr J. R. M. Innes. Some Aspects of Animal Pathology of Interest to the Medical Worker. 5 p.m. Dr T. E. Barlow. The Development and Form of the Bronchial Tree.

ROYAL SOCIETY OF MEDICINE

Section of Experimental Medicine and Therapeutics—*Tues*, 5 p.m. Discussion. New anti-malarials and malarial control. Openers: Brig J. S. K. Boyd, and Prof N. Hamilton Fairley.

Section of Psychiatry—*Tues*, 5.30 p.m. Paper by Dr Russell Davis. Disorders of skill, an experimental approach to some problems of neurosis.

Section of Physical Medicine—*Wed*, 4.30 p.m. Paper by Mr H. E. Griffiths. Analysis of function.

Section of Proctology—*Wed*, 8.30 p.m. A clinical pathological meeting will be held.

Section of Ophthalmology—*Thurs*, 5 p.m. (Cases at 4.30 p.m.) Discussion. Allergy in Ophthalmology. Openers: Mr O. Gayer Morgan, Dr C. J. C. Britton, and Dr J. T. Ingram.

Clinical Section—*Fri* 5 p.m. (Cases at 4 p.m.)

BIOCHEMICAL SOCIETY—At Guy's Hospital Medical School, St. Thomas' (March 15), 2.30 p.m. Annual general meeting. Communications and demonstrations.

BRITISH INSTITUTE OF PHILOSOPHY—At Eugenics Theatre, University College, Gower Street, WC, *Fri* 7.30 p.m. Prof L. J. Russell. Philosophy and Life.

MEDICAL SOCIETY OF LONDON 11 Chandos Street, Cavendish Square, W—*Mon* 8.30 p.m. Discussion. Modern Treatment of Thyrotoxicosis. To be introduced by Dr Horace Evans and Mr Geoffrey Keynes.

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE 26 Portland Place, W—*Wed* 3.30 p.m. Miss Isabel Macdonald. The History of Nursing (Illustrated).

WEEKLY POSTGRADUATE DIARY

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE—At Edinburgh Royal Infirmary, *Tues* 5 p.m. Prof J. H. Gaddum. Introduction of New Remedies.

LONDON SCHOOL OF DERMATOLOGY 5 Lisle Street, Leicester Square, WC—*Tues* 5 p.m. Dr R. F. Bettley. Eczema. *Thurs* 5 p.m., Dr J. L. Franklin. Occupational Diseases of the Skin.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender, and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

CATTERALL—On Feb. 8, 1947, at Preston Royal Infirmary to Elizabeth (née Cormack) wife of Dr S. Catterall, Brockhall, Langho, Lancs., a daughter.

GORDON—On Feb. 8, 1947, at Nuffield House, Guy's Hospital, to Sally (née Allingham) wife of Dr John Gordon of Esher, a son—Andrew Charles John.

LONDON—On Feb. 5, 1947, at Burgh Heath, Surrey, to Stella (née Charter) wife of J. J. London, M.B. B.Ch., a son—John Richard.

LITTLE—On Feb. 12, 1947, at Bangor, N. Wales, to Margaret Neved (née James) wife of Dr D. Crawford Little, a son.

MCBOYLE—On Feb. 16, 1947, to Catherine wife of Dr J. R. McBoyle, 57 Earl Marshal Road, Sheffield, a son, both well.

RIORDAN—On Jan. 18, 1947, to Olga wife of Dr T. P. Riordan of Willoughby, Barley Lane, Goodmayes, a son—Kevin Vaughan.

ROHAN—On Jan. 27, 1947, at Shrublands Nursing Home, to Chris (née Macleod) wife of Dr J. C. Roban, 34 Coombe Road, Croydon, a son—Denys.

VARIAN—On Jan. 11, 1947, at Bath, to Katha wife of Mr S. N. Varian, a son—Nigel Stephen.

WYSE—On Feb. 6, 1947, to Major and Mrs R. W. Wyse, Southlands, Ellesmere Park, Eccles, Lancs., a son.

MARRIAGES

ALLEN-COLINS—On Feb. 1, 1947, at the Savoy Chapel, London, Dr Richard Allen R.A.F.V.R. of Brighthelm to Miss Judy Collins C.S.P. of Bromley.

HARRIS-OSMOND—On Jan. 29, 1947, in Nairobi, Kenya, Norman Francis Harris to Dr L. B. Mary Osmond (née Watch).

HAWKINS-FROLIC—On Feb. 14, 1947, Peter Shaiyle Hawkins M.R.C.S. to Frieda Elizabeth Frolic.

IGHODARO-COLE—On Jan. 25, 1947, at Newcastle-upon-Tyne, Samuel Osarogie Ighodaro M.A. of Benin City, Nigeria, West Africa, to Irene Elizabeth Beatrice Cole M.B. B.S. of Freetown, Sierra Leone, West Africa.

MORRICE-STEWART—On Feb. 6, 1947, at Manchester, George Morrice M.B. Ch.B. Aber. to Margaret Stewart daughter of Dr A. B. Stewart 25 Windsor Road, Manchester 10.

DEATHS

BRIGO—On Feb. 21, 1947, at 11 Sunnysbank Road, Edgerton, Huddersfield, William Edward Brigo M.B. Ch.B. aged 31.

CUMMINS—On Feb. 8, 1947, at Smyrna Beach, Florida, Major Arthur Gordon Cummins M.C. late R.A.M.C.

GRAY—On Jan. 21, 1947, at Totana, Murcia, Spain, Albert G. Gray M.B. Ch.B. aged 70.

LEDGER—On Feb. 7, 1947, at Torquay, A. Vernon Ledger M.D. (formerly of Plymouth).

MCFILL—On Feb. 3, 1947, in London, A. N. R. McNeill D.S.O. M.B. Ch.B. D.P.H. Colonel A.M.S. (ret.) beloved husband of Nora McNeill.

NAVARRA—On Feb. 22, 1947, at Llandudno Hospital, Norman Navarra I.R.C.P. M.R.C.S. D.P.M. formerly Deputy Medical Superintendent City of London Hospital, Dartford, aged 70.

SMITH—On Jan. 30, 1947, at 150 Derby Road, Long Eaton, Nottingham, Reginald Farmery Smith M.R.C.S. L.R.C.P. beloved husband of Helen (Carmichael) M.B. Ch.B.

THE "COSTOCLAVICULAR SYNDROME"

BY

E. D. TELFORD, F.R.C.S.

Emeritus Professor of Surgery, University of Manchester

AND

S. MOTTISRSHAD, M.D., F.R.C.S.

Assistant Lecturer, Department of Anatomy, University of Manchester

While the symptoms which may arise from pressure on the neurovascular bundle as it passes from the thoracic inlet to the arm, although many and varied, are well known and easily recognizable, there is no general agreement on either the site or the mechanics of the compression. There is no doubt that earlier writings have over-simplified the position, and only in recent years does it seem to have been realized that there is no one cause of pressure common to all cases.

The present study is based on (1) the findings at 120 operations undertaken for the relief of pressure on the neurovascular bundle of the arm, (2) examination of the effects of posture of the shoulder girdle on the radial pulse in a series of 120 medical students, (3) the evidence obtained by dissection of 30 bodies.

Operation Findings

These are based on the records of 120 patients who were operated upon by one of us (E. D. T.) between 1908 and the present time for symptoms of pressure on the neurovascular bundle of the arm. Of the 120 cases there were 16 in which the customary symptoms were accompanied, and to a great extent overshadowed, by complications. The remaining 104 cases were of the ordinary textbook type.

The Complicated Cases

Fourteen of these showed extensive arterial thrombosis and in the other two the outstanding complaint was a profuse hyperhidrosis of the hands. In all the cases of thrombosis a well-developed cervical rib was present, but in no single case was any deformity, narrowing, or periarthritis found in the artery where it lay on the rib. In 12 patients the thrombosis extended no higher than to some point between the bifurcation of the brachial artery and the lower border of the pectoralis major. In only two cases was the thrombosis found to extend upwards towards the cervical rib. In neither of these did it reach the rib, but began 1 cm. distal to it in an aneurysmal dilatation of the vessel with much periarthritis.

In two patients the hyperhidrosis of the hands was profuse enough to prevent them following their employment. In one of these the cause was a well formed cervical rib and in the other a taut fibro cartilaginous band representing the forward end of a rudimentary cervical rib.

The Uncomplicated Cases

In 12 of the 104 cases pressure on the lowest trunk of the plexus was due to a strong taut band springing from the pointed tip of a small cervical rib. This band passes downwards and forwards in the anterior border of the scalenus medius. If the anaesthetist is asked to deepen the breathing the lowest trunk is seen to be lifted up by the band, it has in fact in most cases a permanent notch at the point of contact.

A condition which was very similar was found in another 8 cases. The insertion of the scalenus medius was carried forward further than normal with the result that the lowest trunk and the artery were not in contact with the rib but were raised by the V formed on one side by the lateral tendinous edge of the scalenus anterior and on the other by the sharp anterior border of the scalenus medius. In all these cases a partial detachment of both muscles resulted in cure. In 2 cases both girls aged 14, the cause of pressure was a large excelsus boss arising at the point where a well developed cervical rib reached the first thoracic rib. In 8 patients resection of an apparently normal first thoracic rib cured the trouble. In two at least of these there was a distinct scoliosis of the cervico-dorsal spine. In 5 patients no adequate cause was found. They were unrelieved by operation, and may have been instances of brachial neuritis or of prolapsed disc.

The remaining 69 cases showed cervical ribs in various stages of development. In none of these cases was there any naked-eye evidence that either plexus or artery had been damaged by pressure of the clavicle. In the majority the lowest trunk, when freed, showed a permanent notch made by the upper edge of the rib across which it had been tightly stretched. In 3 cases there was an aneurysmal dilatation of the third stage of the subclavian artery starting 1 cm. distal to the rib. With two such cases already mentioned this gives 5 cases of dilatation in 120 patients—a proportion which is in close accord with Husted's (1916) report of 25 instances in 525 patients.

Previous writers have stated that these 'cervical ribs' are in some patients true first thoracic ribs in a deformed and rudimentary state. This observation can be confirmed by taking antero-posterior skiagrams by the moving mandible technique. This permits an accurate count of the cervical vertebrae and should be done in all cases of suspected cervical rib.

Constriction of Axillary Artery by the Median Nerve

A young man aged 23 complained that when his left arm was hanging down by the side he felt numbness and tingling in the hand. This not only gave him much trouble at his work but had led to his being invalided out of the Army. It was noted that depression of the shoulder obliterated the radial pulse but left the third stage of the subclavian artery unaffected.

At operation no cause was found in the neighbourhood of the first rib. A second incision was made below the clavicle through which the axillary artery and adjacent nerves were freely exposed. It was then seen that on downward traction of the arm the artery was compressed by the grip of the two heads of the median nerve and that all pulsation ceased below this point. The opportunity of two incisions, one above and one below the clavicle, was taken to determine what pressure the clavicle could exert on the first rib. A piece of diaphyseal tubing of a calibre equal to that of the artery was threaded between the wounds and behind the clavicle parallel to and in front of the vessel with the shoulder in the normal position. On depression of the shoulder the tube fell out because

clavicle moved away from the rib. In this patient, a broad-shouldered well-built man, there could be no possibility of pressure on the neurovascular bundle in depression of the shoulder.

From the above findings in 120 interventions it is clear that no one happening—e.g., clavicular pressure—can explain all cases of pressure lesions of the plexus.

Movements of the Shoulder in Relation to the Radial Pulse

It is an old observation that in certain positions of the shoulder the radial pulse is diminished or completely arrested. Some writers have taken for granted that the cause of this interference is costoclavicular pressure. For instance, Falconer and Weddell (1943) state that "more than one postural manœuvre involving the shoulder girdle may result in compression of the subclavian vessels." But it is not the subclavian artery that is compressed. A simple observation will show that there is a normal pulse in the first stage of the axillary artery well below the clavicle and that the clavicle has nothing to do with the arrest of the pulse in the arm on pure depression of the shoulder. From this point of view we examined a large series of medical students.

In the extensive literature of cervical rib difficulties arise from a lack of exact definition of the position of the arm and shoulder. In what follows we mean by "depression" a position of the arm held vertically by the side in the posture of carrying a heavy bag, and by "retraction" we imply a displacement of the shoulder backwards, a bracing back of the shoulder as in "throwing a chest". The results are set out in the accompanying Table. From this it is

Table Showing the Effect of Different Postures of the Shoulder in 240 Arms with the Subject in the Erect Position

	Depression of Shoulder	Retraction (Bracing Back) of Shoulder	Extension of Neck (Adson's Manœuvre)	Abduction of Arm		Adduction of Arm Against Resistance
				90°	180°	
70 males (i.e. 140 arms)	56 68 16	53 70 17	118 20 2	131 6 3	75 42 23	18 38 84
30 females (i.e. 60 arms)	30 48 22	23 64 13	94 6 0	91 6 3	35 35 30	9 16 75

seen that in depression of the shoulder there were 116 instances of diminution and 38 of arrest of the radial pulse—i.e., the radial pulse showed some alteration in 64%. In retraction of the shoulder there were 134 instances of diminished and 30 of arrested pulse—i.e., the radial pulse was modified in 68%. In abduction of the arm to 90° the effect is but slight, in only 18 cases—i.e., 7.5%—was any difference noted. In abduction to 180° the proportion of cases in which some alteration was found rose to 54%.

The results when the subject attempts adduction against resistance are of special interest. Whereas in passive abduction to 90° the percentage of alteration is as low as 7.5, when the arm is actively adducted there is a steep rise to 90%. This seems to indicate that some muscular action has come into play. The subject will be referred to later. If the same observations are made with the subjects recumbent it is found that there is no difference in the results from depression of the shoulder in the erect and recumbent positions. This finding suggests that the cause is purely mechanical and unaffected by gravity. In the recumbent position the effects on the pulse in abduction to 180° are noticeably slighter. This may be due to the effect of gravity.

Anatomy of the Axillary Artery

Bearing in mind the fact that the arrest of the pulse in the axillary artery this region was dissected in 18 bodies. In 12 out of 18 dissections the axillary artery at the level of the second rib took an abrupt lateral turn for 1.5 cm and then again changed direction to pass directly down into the arm. The trunks of the plexus were arranged round the first part of the artery in the following manner: the superior trunk was placed postero-lateral, the middle trunk posterior, and the inferior trunk postero-medial to the vessel. The lateral and medial heads of the median nerve were given off the plexus just at the point where the artery made its S turn opposite the second rib. They lay one in front and the other behind the artery, embracing it in a scissor-like grip which when the shoulder was depressed by traction on the arm could be seen to constrict the vessel. In the remaining 6 subjects the lateral curve of the vessel occurred opposite the first rib. Thus the superior trunk lay anteriorly, the middle trunk postero-medially, and the inferior trunk medially to the artery. The two heads of the median nerve are, in this type, so disposed that they cannot constrict the vessel however much the shoulder is depressed.

The above relationships differ from those usually described owing to the fact that our dissections were made with the arm close alongside the trunk. In the usual position for dissection—i.e., abduction to 90°—the S bend of the vessel is straightened out. The heads of the median nerve are in relation to the third part of the artery when the arm is abducted but to the junction of the first and second parts when the arm is by the side of the body.

The evidence afforded by the operation described above and by observations from our dissections would seem to suggest that the arrest of the radial pulse in depression of the shoulder is due to compression of the artery by the heads of the median nerve. It is not without significance that these postures caused changes in the pulse in two-thirds of the students and that a relationship in which such constriction was mechanically possible was found in 12 of 18 bodies.

The explanation of the arrest of the radial pulse in abduction is not easy. Dissection shows that with the arm alongside the body the neurovascular bundle lies at a distance of 3 to 4 cm below the coracoid process. As the arm is abducted the distance alters little, for although the bundle rises slightly the coracoid is elevated at its tip and moves backwards owing to rotation of the scapula. This movement carries the pectoralis minor upwards and backwards so that the neurovascular bundle is obliged to move slightly backwards under this muscle to reach the abducted arm. During abduction the humerus rotates laterally to prevent the impingement of the greater tuberosity against the acromion. The humeral head protrudes into the lax part of the joint capsule, causing a prominence under the tendon of the subscapularis. The neurovascular bundle as it emerges from under the pectoralis minor is pressed against the head of the humerus covered by the tendon of the subscapularis. Division of the pectoralis minor at its insertion frees the bundle, and its close apposition to the humerus is relieved.

It has already been shown that, whereas simple abduction of the arm to 90° interferes with the radial pulse in 7.5% of subjects, the ratio rises at once to 90% if the subject forcibly adducts the arm. By this action the pectoralis minor and subscapularis would be tightened to an extent sufficient to cause compression of the axillary artery. Whilst making this suggestion with reserve we would state definitely that in none of our dissections did we find any

evidence to support Wright's (1945) contention that trouble may arise from forcible contact with the coracoid process itself

Movements of the Clavicle in Relation to the First Thoracic Rib

The relations between the clavicle and the first rib were studied in 25 bodies. In these formalized bodies it is necessary to cut across a certain amount of muscle if full movement of the clavicle is to be obtained. To guard against the possibility that this cutting of muscle might falsify the findings, five fresh post-rigor bodies were examined in the post-mortem room. There was, however, no difference in the findings in the two sets of bodies.

When the shoulder girdle is depressed by pulling the arm downwards alongside the trunk the clavicle describes an arc moving downwards and forwards so that the further the shoulder is depressed the further forward the clavicle moves, widening the interval between the clavicle and the first rib. At no point in this excursion could the clavicle be made to impinge on the subclavian artery, but the interval between the two bones is narrowest (1.5 cm.) when the clavicle lies opposite the upper border of the first rib. In order to press the clavicle directly backwards on the first rib it is necessary to open the sternoclavicular joint and to sever the intra-articular disk.

As regards the plexus itself depression of the shoulder causes the superior and middle trunks, together with the contribution from the seventh cervical nerve to the long thoracic nerve (nerve to the serratus anterior), to be tightly stretched across the tendinous edge of the scalenus medius. The inferior trunk is pulled hard down into the angle of junction of the scalenus medius and the first rib. It is not possible by this manoeuvre to compress the artery against either of the scaleni. The vessel can still be moved freely from side to side in the interval between the scaleni, but the S curve is abolished.

When the shoulders are retracted the acromial end of the clavicle rises and the bone lies across the root of the neck above the level of the first rib. The clavicle now makes an angle of 30° with the first costal cartilage. In this position the tendon of the subclavius compresses the subclavian vein against the first rib, but the clavicle itself does not press on that vessel. The middle third of the clavicle pushes the neurovascular bundle backwards against the anterior border of the scalenus medius, and in the presence of a resistance—e.g., a cervical rib or an abnormally placed first rib—could compress the bundle.

The excursion of the clavicle in abduction shows little or no difference from that already described in retraction.

Discussion

The literature of brachial plexus pressure has increased considerably in recent years. This is due in part to the striking rise in the number of cases of paraesthesia of the hand and arm in middle-aged women who are overworked, underfed, and spend much time carrying shopping baskets. The general tendency is to suggest that the troubles are due to compression of the plexus between clavicle and first rib. This is a pure supposition unsupported by any anatomical evidence. Some confusion in the literature further arises from papers which base definite opinions on an insufficient number of cases or include abnormal types—e.g., scoliotics. Moreover, not enough attention has been paid to a separate analysis of the movements of depression, retraction, and abduction.

In a normal person standing in the erect position the clavicle is presumably not pressing on the bundle. The moment that pure depression of the shoulder begins the

clavicle moves away from the bundle, and the further the depression the further is the clavicle away. It seems clear, therefore, that symptoms referable to the plexus arising in depression of the shoulder are not due to pressure by the clavicle, and we believe that they are caused purely by drag on the nerve cords. In this position of the limb we have shown that the plexus is stretched taut over the edge of the scalenus medius, and this is especially likely to happen where that muscle has its attachment carried forward further than usual on the first rib.

It is otherwise with retraction and with abduction. Here the clavicle in its middle third presses the neurovascular bundle against the scalenus medius. With a normal muscle such pressure is trivial, it possibly explains those cases where prolonged abduction of the arm, as in dressing the hair, causes temporary 'pins and needles'. Should, however, the resistance be stiffened by a cervical rib or an abnormally high first rib the pressure might easily become more serious.

It seems likely that the patients may be divided into two groups. In one, the smaller group, the pressure is cervical, and in this type the symptoms are those of the whole plexus pressure. They are produced by retraction and abduction, and are felt at places from the deltoid region down to the hand. In the second group the symptoms are referable predominantly to the distribution of the lowest trunk and are due to hanging up of the plexus over a cervical rib, a band, the scalenus medius or an abnormal first rib when the shoulder is depressed. We believe this to be much the larger group.

Summary

An account is given of the findings in 120 operations and 30 dissections with observations on 120 students.

No one mechanical cause can explain all cases. Damage by pressure of the clavicle cannot happen in pure depression of the shoulder but is a likely event in retraction and abduction if cervical rib or abnormal first rib be present. These cases will probably show whole plexus symptoms.

The most common cause of symptoms is the hanging up of the plexus on a cervical rib or other mechanical obstacle. These cases are likely to show lowest trunk symptoms.

The phenomenon of alteration in the radial pulse on movements of the shoulder is due to causes distal to the clavicle. It has nothing to do with the costo-clavicular syndrome.

We desire to express our indebtedness to members of the anatomy staff, and especially to Drs. E. L. Patterson and T. E. Barlow, for their help in this inquiry.

WATER AND SALT DEPLETION*

BY

H L MARRIOTT, CBE, MD, FRCP

Physician with Charge of Out-patients Middlesex Hospital

Comparison of Effects

The main differences are shown in Table V. Their theoretical explanation, as already suggested, appears to derive from the contrast in conditions of extracellular-fluid osmotic pressure. In pure water depletion (Fig 4A) the extracellular fluid tends to become hypertonic and its volume to be maintained by withdrawal of water from the cells. In consequence of the relative normality of the plasma volume, oligæmic symptoms, such as lassitude,

TABLE V—Comparison of Effects of Water and Salt Depletion

Manifestation	Pure Water Depletion	Pure Salt Depletion
Dehydration	+++ primary or simple	+++ secondary or extra cellular
Thirst	+++	Absent
Lassitude	+	+++
Orthostatic fainting	Absent till late	+++
Urine volume	Scanty	Normal till late
NaCl in urine	Often +	Always absent except in Addison's disease
Vomiting	Absent	May be +++
Cramps		
Plasma NaCl	Slight increase or normal	Diminished +++
Blood urea	+	+++
Plasma volume	Normal till late	Decreased +++
Haemoconcentration	Not till late and slight	+++
Blood viscosity	Normal till late	Increased +++
Blood pressure		Fall +++
Water absorption	Rapid	Slow
Mode of death	? due to rise of osmotic pressure	Peripheral circulatory failure

giddiness, fainting, and fall of blood pressure, are absent or do not develop until a late stage. Thirst is pronounced because of cellular desiccation. In pure salt depletion (Fig 4B) the extracellular fluid tends to become hypotonic and so water is not sucked from the cells and there is little or no thirst. The kidneys, working to preserve isotonicity of the extracellular fluid, excrete water, therefore, while water is being ingested and absorbed, urine volume is not significantly decreased, and may be increased. The volume of the extracellular fluid falls. The decrease of plasma volume causes prominent symptoms of peripheral circulatory failure due to oligæmia and increase of blood viscosity.

Mixed Water and Salt Depletion

Pure water depletion may be defined as reduction below normal of total body water without significant reduction of

total body salt, pure salt depletion, as reduction below normal of total body salt without reduction of body water beyond that which is inevitable from loss of extracellular osmotic pressure. Mixed water and salt depletion may be defined as reduction below normal of total body water and total body salt, the water reduction being greater than that consequent upon the secondary dehydration of salt depletion. This occurs in patients in whom there have been abnormal losses of secretions *without free intake of water*, the water loss tends to outstrip salt loss because the secretions lost are either isotonic (gastric or intestinal juices) or hypotonic (saliva, sweat), and, in addition, there is extra depletion of water in the continuous unavoidable losses, averaging about 1.5 litres daily, which occur from the skin and lungs and in the urine. Patients suffering from mixed depletion, as above defined (water loss in excess), have a mixture of the symptoms of pure water and of pure salt depletion. This is because the extracellular-fluid volume is diminished, due to the reduction in total sodium and chlorine, but there is also a tendency for the shrunken extracellular fluid to be hypertonic owing to the disproportionate water loss. The tendency to hypertonicity causes some with drawal of water from the cells. The clinical picture, therefore, is such that patients show the circulatory and other features due to reduction of extracellular-fluid volume, but are also thirsty, have dry mouths, and have early oliguria.

Any condition causing secretion losses unaccompanied by adequate water intake will result in mixed depletion. Cases of acute vomiting provide the commonest examples. In protracted vomiting, such as occurs in pyloric stenosis, the effects of salt depletion tend to dominate the picture because water intake usually goes on until the late stages, so that there is a prolonged phase of selective drain of chlorine and sodium. Estimations of plasma concentrations of sodium and chlorine are even more fallacious as indicators of total loss of these ions in mixed depletion (water loss in excess) than in pure salt depletion, because of the tendency to hypertonicity in the diminished extracellular fluid. In any case, plasma chlorine estimations in vomiting, as already pointed out, are no guide to the concentration of sodium ions, because of the much greater loss of chlorine than of sodium (see Fig 8). In mixed depletion due to vomiting it is possible for the concentration of sodium ions, largely partnered by HCO_3 , and the plasma osmotic pressure to be raised when the concentration of chlorine ions is decreased. In severe diarrhoea without vomiting (see Fig 8) the converse may be true. The concentration of chlorine ions may be a little lower, or normal, or even raised while the concentration of sodium ions is decreased. Rogers (1921) found serum chlorides in cases of cholera before treatment to be as high as 0.79%.

Occurrence of Pure and Mixed Depletions in Practice

Pure water depletion is frequent in the circumstances already described, pure salt depletion or mixed water and salt depletion, however, are still more common because of the many causes of vomiting and diarrhoea. It is necessary to enumerate only a few of these causes to realize the frequency with which water and salt may be lost from the body. For example, vomiting may occur from gastritis, gastro-enteritis, appendicitis, pyloric or intestinal obstruction, and peritonitis, associated with pregnancy, after administration of anaesthetics, in alcoholism, in uraemia, in diabetic ketosis, in sea-sickness, and in such intracranial conditions as concussion, meningitis, cerebral tumours, and cerebral vascular lesions. Diarrhoea may occur from enteritis and colitis, from dysentery and cholera, from pancreatic insufficiency, in sprue, from ulcerative and neoplastic conditions of the intestines, and in patients in whom

* Conclusion of the Croonian Lectures delivered at the Royal College of Physicians London on Dec 3 and 5, 1946. Parts I and II appeared in our issues of Feb 15 (p 245) and March 8 (p 285).

ileostomy has been performed (Cave, 1946). The special frequency of vomiting and diarrhoea in children is well known, their particular vulnerability to water and salt loss has already been mentioned.

The present frequency of pure salt depletion resulting from the treatment with water alone in those who have lost both salt and water has been emphasized. In recent months I have seen such unrecognized salt depletion in ten patients: two with severe gastro-enteritis, one with ulcerative colitis, two with chronic alcoholism, and in five after operation (gastrectomy, cholecystectomy, ileostomy, and two gastro-enterostomies). All ten had been diagnosed as suffering from dehydration. Four of the five post-operative cases had been treated with intermittent spells of gastro-duodenal suction drainage. All the patients had been on forced fluids, and intake and output charts were being kept. All had become extremely ill and were drowsy, apathetic, or stuporous. None complained of thirst, and none had chloride in the urine. All had lowered blood pressures, in three the systolic pressure was below 90 mm Hg. The blood urea levels were raised, the highest being 280 mg per 100 ml. After the diagnosis of salt depletion had been made, all, except one of the alcoholics, were treated by the administration of large amounts of intravenous saline (5 to 9 litres of isotonic saline) and all except the untreated alcoholic and the ileostomy case (plasma Na 242 mg %), rapidly recovered. In the Tropics I saw many instances of the salt-depletion syndrome, from simple sweating to sweating plus vomiting and diarrhoea, develop in patients suffering from various forms of medical and surgical illness.

The failure to recognize the true nature of the salt depletion syndrome often occurs because the patient's deterioration is explained in terms of pathological states which are essentially secondary but are mistakenly thought to be primary. Thus in many cases the frequent high blood urea levels lead to a diagnosis of uraemia. The tendency to vomiting in the late stages sometimes suggests a diagnosis of acute dilatation of the stomach or paralytic ileus, the lowered blood pressure and the manifestations of peripheral circulatory failure may cause the condition to be ascribed to 'shock'.

Diagnosis

The differential diagnosis between water and salt depletion and mixed depletion is a comparatively easy matter, depending on recognition of their different modes of causation and awareness of the facts of their clinical and pathological differences.

Estimation of the chloride content of the urine is a most important diagnostic test. Qualitative diagnosis of the type of depletion is not enough. It is essential also that the attempt should be made to arrive at a quantitative diagnosis of the amount of the deficiency of water or salt or of water and salt.

Prevention

This, again, is mainly a matter of awareness of the possible development of water and salt depletion. Fortunately, this state of alert anticipation now generally exists so far as water is concerned. It has become nearly as automatic to chart fluid intake and output of seriously ill patients as to record their temperature and pulse rate.

The best guarantee that water intake is sufficient is an adequate urine volume, in regard to which there are two points of practical importance. The first has already been mentioned: it is that in patients who have inefficient kidneys, incapable of secreting concentrated urine, the daily output of urine may need to be not less than 1.5 litres. Apart from permanent renal inefficiency, temporary

damage is frequent in illness, therefore it is seldom advisable to be satisfied with a urine volume of less than 3 pints or 60 oz (1.7 litres) daily. The point is that, when gross secretion losses are occurred, 24 hours is too long a unit of time to allot for a review of the output within its span the patient can die of dehydration. In such cases the urine volume and chloride content should be reported to the doctor eight-hourly. The aim should be a pint (570 ml) per eight hours.

We are not generally aware of the potential hazard of salt depletion. However, it is to be hoped that its importance will soon be realized in this country in all cases suffering losses of alimentary secretions. In the Tropics when patients are sweating its menace enters into every form of medical and surgical illness. Whenever salt depletion may occur, the routine testing of the urine for chloride is a matter of first importance—more important indeed than the taking of the temperature or the counting of the pulse, not, of course, that these essential procedures should be omitted. The aim in adults should be an NaCl concentration of 3–5 g per litre.

Treatment of Established Depletions

At the outset it is desirable to call attention to the grave consequences of wrong treatment. In pure water depletion patients require water and water only until the deficit has been replaced. The administration of isotonic saline tends to increase existing extracellular hypertonicity, to intensify thirst and to add to the difficulties of already embarrassed kidneys. It may be lethal (McCance and Young (1944) may be quoted). Let us suppose that a patient is unable to take anything by mouth and that in consequence, he is given during 24 hours 1,500 ml of normal saline intravenously—that is, 1,500 ml of water and (approximately) 15 g of salt. He will require 1,000 ml of this water to make good the unavoidable losses from his lungs and skin, and so his kidneys will have the impossible task of excreting 15 g of salt in 500 ml of water. The casual administration of saline to young infants is even more dangerous than it is in adult life, for the infant kidney is much less capable of dealing with the superfluity of salt (Young, Hallum and McCance 1941; McCance and Young, 1941). Wrong treatment in salt depletion on the other hand, chiefly consists in failure to administer saline. In consequence the state of salt deficiency is not relieved and the patient may die of oligemic circulatory failure. It is probable that hundreds, if not thousands of patients in this country die annually from salt depletion. In the Tropics the mortality must be much greater.

Though the common and most important therapeutic error in salt depletion is the negative one of omitting to give salt, sometimes there are serious consequences due to the positive error of pressing the administration of water beyond the amount required to compensate unavoidable water losses. When the patient is collapsed and the pylorus closed, the administration of much water by mouth may lead to overfilling of the stomach and to regurgitation or vomiting of the gastric contents, in which the patient may drown, so gravely depressed is the cough reflex. I have seen it happen. Again, when the stage of low blood pressure has been reached anuria develops. Water introduced into the blood stream, whether by absorption from the alimentary tract or direct as intravenous glucose solution cannot then be excreted in the urine and may cause death from water intoxication (Weir, Larson, and Rowntree, 1922; Helwig, Schutz, and Curry, 1935). Since the plasma and tissue fluid are hypotonic the water must enter the cells. It is probable that resurgence of the cerebral cells is the cause of death, which may be preceded by convulsions. It

is well known that "stokers' cramps" of salt-depletion heat exhaustion particularly tend to be precipitated by the ingestion of large amounts of water

The special parenteral methods of administration of glucose solution subcutaneously and intraperitoneally—for example, in infants—may precipitate collapse in severe salt depletion by removal of salt from the already depleted plasma. This is because sodium and chlorine ions rapidly diffuse into a tissue depot of injected glucose solution (Darrow and Yannet, 1935). The administration of potassium salts is dangerous in sodium depletion. (In this connexion one has only to remember their danger in Addison's disease.) Sometimes the error of giving potassium to salt-depleted patients who are receiving sulphonamides arises from the routine administration of potassium citrate to alkalinize the urine. In such cases sodium citrate should be used.

Enough has been said about the consequences of wrong treatment to show that there are serious pitfalls in the treatment of different types of dehydration due to water and to salt depletion. The subject is far from being as simple as is often assumed—an assumption which may lead to the control of water and salt administration being left to nurses or junior residents. The essential principle in the treatment of water and salt depletion is that the patient shall be given water or salt, or both, in the amounts that each is lacking. Therefore, as in all conditions, correct diagnosis—in this instance quantitative as well as qualitative—is essential to correct treatment. The facts and principles on which diagnosis depends have been dealt with and need not be recapitulated. The main questions which arise in practical treatment are (1) What fluid should be administered? (2) How much? (3) By what route? (4) At what rate?

1 The Fluid to Administer

In water depletion, water should be administered by mouth or per rectum, unless the circumstances of the case compel the use of alternative routes—intravenous, subcutaneous, or intraperitoneal. If one or other of these latter routes must be used, then the best vehicle for water is isotonic glucose solution (5%). In salt depletion isotonic saline solution (0.85%) should be administered when the salt deficiency is giving rise to symptoms and while chloride is still absent from the urine. In very severe salt depletion, with vomiting and circulatory collapse, intravenous administration is indicated, as other routes may be too slow to save life, while oral administration carries the special risk of drowning or, short of drowning, of infecting the bronchial tree. When symptoms are relieved, or when chloride reappears in the urine, isotonic saline should be discontinued in favour of hypotonic saline. It is never desirable to continue isotonic saline administration longer than is necessary, because as soon as salt depletion is relieved there is a tendency for patients receiving isotonic saline to retain sodium and chlorine out of proportion to water (Coller, Job, Vaughan, Kalder, and Moyer, 1945). For adults the hypotonic concentration of choice is 1/2 isotonic (0.425%) until the salt balance appears to be fully restored, and then, if food is not being taken and salt intake must be derived from fluid 1/3 isotonic for maintenance. If parenteral routes are being employed these strengths may be achieved by mixing one part of isotonic saline solution with one or two parts of isotonic glucose solution. In the case of children particular care should be taken not to continue too long with isotonic saline; indeed, some authorities consider the possible dangers to infants to be so great that isotonic saline should never be used. Suitable hypotonic concentrations for infants are 1/4 or 1/5 isotonic—that is for parenteral use one part of isotonic saline mixed with three or four parts of isotonic glucose solution. In mixed water and salt depletion, or if there is any doubt as to the nature of the depletion, the patient should from the start receive hypotonic saline in the strengths above indicated.

It may be asked whether simple saline solution is sufficient to repair electrolyte deficiencies consequent upon loss of alimentary secretions, and, in particular, whether or not adjustments in the nature of the solution should be made to rectify alterations in the acid-base balance. This question is not really finally settled but most authorities would I think, agree with Gamble (1942) that saline or saline mixed with glucose solution is all that is needed. For a discussion of the considerations involved Gamble's monograph should be consulted.

2 Amount of Fluid

The essential principle is that the amount given, whether of water or saline, shall be enough to restore the patient to a normal state of balance. As shown in preceding sections, the initial deficit in a 70-kg (or 11-stone) man may range up to a maximum of 10 litres (18 pints) of water in water depletion or the equivalent of 10 litres of isotonic saline in salt depletion. The clinical criteria for the rough estimation of the volume of depletion have been given. In addition to the initial deficit, allowance must be made for losses going on during the period of fluid administration. The best check on restoration of water and salt is provided by eight hourly measurements of the volume of urine and estimation of its chloride content. The aim per eight hours in an adult should be a urine volume of not less than a pint (570 ml) and a salt content of 3 to 5 g per litre. In infants urine measurement and testing for chloride present special practical difficulties. Yet they would seem to be even more important than in adults, because infants die so quickly from fluid depletion and because their kidneys have not the same power of correcting therapeutic errors. I have not the practical experience needed to attempt to define figures. All that can be said is that infants need to pass relatively much larger volumes of urine with lower chloride content.

During the intravenous administration of saline some NaCl may spill into the urine even though the patient is still grossly salt deficient. For this reason if testing the urine shows the presence of chlorine it is wise to discontinue the saline, substituting glucose solution if it is desired to continue a drip infusion, and then half an hour and an hour and a half later instruct the patient to pass urine. The 30 minute specimen should be discarded and the 90 minute specimen tested for chlorine.

In fluid restoration a quantitative attitude of mind is essential, and it is necessary to realize clearly the considerable magnitude of fluid deficit which may be present in a case of water, salt, or mixed depletion. Fortunately we are passing out of the days when patients deficient of perhaps 1½ to 2 gallons (6.8 to 9 litres), and suffering continuing losses, received a pint or two of fluid, though the approach is still often too homoeopathic.

3 Route of Administration

Some remarks concerning this question have already been made. In severe salt or in mixed depletion the intravenous route should be used and the continuous drip method employed. Otherwise, whenever circumstances permit, the oral route is the best. If the patient has difficulty in drinking a most valuable device, is the transnasal intragastric drip. This method consists in fluid administration, by continuous drip, through a Ryle's tube passed via the nose into the stomach. It was particularly exploited by Ransome, Gupta, and Paterson (1944), who have recorded their experience with 355 acute medical cases, and their paper should be consulted for details of the very simple technique. Their work was done at a large military hospital in Assam, and more than 100 of the cases were in-patients in various degrees of coma from cerebral malaria. The nursing facilities were far from being on the scale of British civil hospitals yet the method was found easy to run in practice. Nauth-Misir (1946) has written on the use of this method in infants, in whom it would seem to be particularly useful. The technique of the continuous intravenous drip, originated by Matas (1924), is too well known to need comment.

I would like to draw attention to the value of rectal fluid administration when properly carried out in accordance with the principles of Murphy (1909, 1916). The technique and also other methods of parenteral fluid administration have been described (Marriott and Kelwick, 1937).

4 Rate of Administration

The desirable rate of fluid administration depends on the state of the patient. The need for rapid intravenous administration arises in patients suffering from peripheral circulatory failure due to severe salt depletion or mixed depletion. Such cases are urgent emergencies and the rate of administration for adults should be of this order: the first pint in 10 minutes, the second pint in 15 minutes, the third pint in 20 minutes, and the fourth pint in 30 minutes, then a pint every two hours till the blood pressure is restored to normal. Thereafter a pint every four hours (more under tropical conditions). In infants the quantities should be on a similar scale in proportion to body weight. In less acute depletions slower restoration is indicated. However an adult suffering from a degree of either water or salt depletion sufficient to cause symptoms will need to receive within the first 24 hours a minimum of a gallon (4½ litres) of appropriate fluid. Watch must always of course be kept on urine excretion and for signs of oedema, especially pulmonary oedema.

Complicated Cases

Special difficulties and dangers are associated with fluid administration to patients who have suffered from acute haemorrhage or who are anaemic or hypoproteinaemic (Power, Pedersen, and Maddock, 1942), to those in whom anoxia or toxæmia has increased capillary permeability especially the permeability of pulmonary capillaries (Daly 1946), and to those whose kidneys are badly damaged. In all such cases most careful consideration must be given to what is done, and very close watch maintained for the development of pulmonary oedema during fluid administration. Patients who have suffered from haemorrhage should receive preliminary blood transfusion to restore blood volume. Those who are seriously anaemic should if possible have their haemoglobin restored by drip transfusion (Marriott and Kekwick 1935-1940) while fluid administration by other routes proceeds. Patients with hypoproteinaemia should if possible similarly receive plasma transfusions, and anoxic patients should be given oxygen.

Water and salt are, perhaps, practically the most important substances it is in our power to administer. They can be so used that they can achieve seeming miracles, or they can be so misused as to lead to a fatal issue. Their proper use is not the simple matter it is often assumed to be. The true approach to understanding is one of humility.

Postscript

A few days before these lectures were delivered an article by Prof E B Verney appeared (*Lancet* 1946, 2, 739 and 781) which I did not see until later. In this important paper, recording much precise experimental work, it is shown that liberation of posterior pituitary antidiuretic hormone is determined by the osmotic pressure of the arterial plasma. The hypothesis is advanced that changes in this pressure are appreciated by 'osmoreceptors' which are continually engaged in controlling the antidiuretic function of the pituitary. Verney's work thus confirms, from another angle the paramount importance of the maintenance of the isotonicity of the extracellular fluid. It also implies that renal activity in preserving such isotonicity may be largely or wholly dependent on the functional linkage between the neurohypophysis and the kidneys. The influence of the pituitary antidiuretic hormone on renal water excretion has of course been known for many years—largely due to the researches of Verney. However his latest work, showing that the production of this hormone is related to plasma osmotic pressure, makes a big forward step. His findings do not affect the clinical views expressed in these lectures, but they are important in helping to reveal the physiological mechanism by which the kidneys guard the osmotic constancy of the 'internal environment'.

I wish to thank Prof J L Gamble, of Harvard, for his generous permission to reproduce his diagrams (Gamble, 1923, 1942) showing the composition of the body fluids. His concise monograph (1942) is a masterpiece of lucid verbal and diagrammatic exposition. To Prof R A McCance I am indebted for supplying references, and would like to pay tribute to the great importance of the work he has done in this field. I wish also to thank Dr D A K Black, Dr R A Kekwick, and Dr N F MacLagan, who have kindly given

THE SWALLOWING OF FOREIGN BODIES

BY

W LINDESAY NEUSTATTER, MD, BSc, MRCP
 Late Lieut-Col RAMC, Physician for Psychiatry Queen Mary's Hospital for the East End and the Royal Hampshire County Hospital

Recently an epidemic of foreign-body swallowing resulted in the admission of 11 cases into a military hospital in the course of a few months*. For the purpose of investigation the 11 "swallowers" were compared with 11 psychopaths and 11 clearly stable prisoners as controls. The psychopathic controls were the usual unstable, impetuous, emotional types with overflowing crime sheets, the normal controls were deserters, most of them young men whose nerve had gone during the course of the Italian campaign, but who had otherwise blameless records and were well-behaved in prison. I interviewed the prisoners alone, if necessary several times. I explained that the inquiry was a medical one, that nothing they said would be held against them, and that they had nothing to gain personally, though ultimately all prisoners might benefit from the information obtained.

* See Major Hallett's paper, which includes cases not in this series. Some of my series had had operations in other hospitals previously, hence any discrepancies.

Results

The most striking fact which emerged was that the "swallowers" (Group I) fell very definitely into two sub-groups (a) those who had only pretended to swallow, or who had swallowed harmless objects in an entirely calculating manner in the hope of being sent to hospital, which was outside the prison, and (b) those who had swallowed objects when in a highly emotional state with a considerable degree of depression present. In the latter group operation was necessary on various occasions, the six of them having had 15 abdominal operations in all (over a period of months or years) compared with two operations needed by the former. The accompanying tables make a comparison of the swallowers and the control groups on matters which I hoped would throw light on the causes of the swallowing, to facilitate ease of comparison the subgroups Ia and Ib are compared on a basis of 11 (see the figures in parenthesis).

Table I (A) shows the preponderance of bad home conditions in childhood. As the items enumerated—

TABLE I

	Group Ia* (5 Cases)	Group Ib (6 Cases)	Group II (11 Cases)	Group III (11 Cases)
No. of operations required	2 (4)	15 (27)	0	0
A Home conditions in childhood				
Father violent	0	3 (6)	1	0
alcoholic	0	2 (4)	2	1
brutal	1 (2)	3 (6)	3	1
Parental disharmony	1 (2)	2 (4)	4	1
separation	0	1 (2)	1	1
Total	2 (4)	11 (20)	11	4
B Youthful instability				
Truancy from school	1 (2)	2 (4)	3	0
Adolescent delinquency	1 (2)	3 (6)	4	0
Violent tempered child	2 (4)	2 (4)	1	0
Nervous child	2 (4)	1 (2)	2	0
In reformatory	2 (4)	0	2	0

* The results showed Groups Ia and Ib so essentially different that the comparison of figures for the total of Group I seemed valueless. The figures in parenthesis are on a basis of 11 (approx).

alcoholic father, matrimonial disharmony, etc.—are various aspects of an unsatisfactory home situation I felt it legitimate to add these. It will be seen there is the usual preponderance of these factors in the psychopaths, whether swallowers or not. Table I (B) shows a similar but less striking difference in traits indicative of instability in childhood. The matters recorded in Table II were designed to

TABLE II—Adult Instability and Affective Reactions

	Group Ia (5 Cases)	Group Ib (6 Cases)	Group II (11 Cases)	Group III (11 Cases)
Anxious in prison	1 (2)	6 (11)	4	3
Depressed	0	6 (11)	3	2
Emotional	2 (4)	4 (8)	4	1
Aggrieved	0	2 (4)	1	0
Paranoid attitude	0	2 (4)	1	0
Aggressive	1 (2)	3 (6)	1	0
Harassed and drawn faces	1 (2)	6 (11)	3	1

reveal traits indicative of markedly emotional personalities. Anxiety and depression were recorded from subjective complaints, the other items were my observations. It will be seen that there is a steady decline in the incidence of affective reactions from Group I to Group III, but the most striking difference is between Groups Ia and Ib. Of the latter group of 6 "true swallowers," 6 were anxious and depressed, 4 had drawn faces, and 4 were very emotional, in contrast to 1, 0, 1, 2, for the same traits in Group Ia.

Table III deals with factors which my previous experience of prisoners suggested might be of aetiological significance—namely, treatment by the prison staff, prohibition of smoking, and the food. It will be seen that the results

TABLE III—Aetiological Factors

	Group Ia (5 Cases)	Group Ib (6 Cases)	Group II (11 Cases)	Group III (11 Cases)
Complaints				
Of bad treatment in prison	0	1 (2)	2	0
Of no smoking	3 (6)	4 (8)	4	5
Of poor food	1 (2)	2 (4)	2	0
Effects of solitary confinement				
Severe	0	4 (8)	1	1
Moderately severe	1 (2)	2 (4)	3	0
Dislike	2 (4)	0	4	4
Indifference	2 (4)	0	3	6

were much the same for all the groups, the ban on smoking heading the list. It is noteworthy that out of 33 prisoners, 22 of whom had been selected as the most recalcitrant, only 4 should allege unsatisfactory treatment and 5 complain of the food—results which reflect favourably on the prisons concerned.

Solitary Confinement—The prisoners were locked in their cells from 4.30 p.m. to 6 a.m., and for dinner. Their reactions to this have been recorded as follows: (1) Severe and moderately severe, referring to the intensity and duration of depressive reactions, with or without anxiety, the latter did not exist without the former. The depressions were not "psychotic"—i.e., there was no retardation or delusions, etc.—but both severe and moderately severe reactions would ordinarily have caused these patients to be admitted for observation for their own safety. (2) Dislike—a term used to designate a natural but not pathologically intense objection to solitary confinement. (3) Indifferent—some prisoners being apparently completely unconcerned about it. Solitary confinement produced the greatest reaction among the true swallows, and, as the histories show, appeared to have been the most immediate precipitant factor, for 4 were severely and 2 moderately affected—i.e., all were reacting to a pathological extent. The other psychopaths—Group II—came next: 3 were moderately and 1 severely affected—the last a depressed schizoid type who made a determined attempt at suicide. Only 1 normal control was severely affected and none moderately. Again it is noteworthy that of the pseudo-swallowers, only 1 had a moderately severe reaction and none a severe one.

An attempt was made to carry out intelligence and personality pointer tests, similar to those used at Officers' Selection Boards. These resulted in failure. Lack of time made testing in groups necessary, with the result that the psychopaths and swallows mostly behaved so preposterously—ranging from a sullen refusal to co-operate to giggling like hysterical schoolgirls—that no results were obtained. But it gave me an illuminating insight into the difficulties of the prison staff.

Discussion

The numbers concerned in this inquiry are too small for statistical analysis. The results, however, are in keeping with my own impressions over a longer period, but their validity is also largely dependent on the honesty of the prisoners' statements. Apart from lack of insight, one naturally suspects that these might be influenced by fear or by a desire to curry favour. But I had made it quite clear that the men had nothing to gain personally, nor would those in charge be informed of anything which might cause prejudice, and their case histories would be recorded anonymously. The prisoners seemed to be replying honestly, and the preposterous behaviour of the psychopaths was not suggestive of any feeling of intimidation. Some representative case histories should assist in assessing the results.

Group Ia—One man was in prison for absence and stealing, he was plausible and took prison philosophically.

He admitted he had pretended to swallow some wire, but "would not have been so silly" as really to swallow anything harmful. Another was in prison for robbery with assault. Deported from Australia as undesirable when a youth, he struck me as a hard, tough, calculating type who would be undeterred from any crime he could get away with. He readily admitted he had lied about swallowing, remarking spontaneously that he knew it was dangerous. Another, who swallowed a toothbrush and buttons, said he would not have done so had he expected to lose the whole of his remission. This remark sums up the attitude of this group: they would do anything that gained them something, provided the disciplinary consequences were not too severe and that they did not really injure themselves.

Group Ib—One man swallowed foreign bodies three times. His parents had separated, he had been a hot-tempered and delinquent boy, who, when his sisters married men he did not like, stole their cutlery "to try and break their homes up." He felt that his family was against him, that "someone would get him," and asserted that a theft of mail for which he was in prison was due to a desire to make "fellows at the unit who had victimized him suffer." He swallowed as "he could stick it no longer in prison." When I saw him after his second attempt he said "I wish I had succeeded. If they put me back in that hell I shall do it again," which he did, necessitating a third abdominal operation. On examination he was backward and though only 26 his face was heavily lined; he was tense with emotion, spoke of his "wrongs" with great feeling and exhibited dread of solitary confinement. Another man who swallowed three times had left home at 14 as he had a violent alcoholic father who beat him. He had twice been a corporal and twice imprisoned for stealing and had been punished for numerous absences. Recently he had improperly used an Army vehicle to drive about a girl "he was very much in love with," and finally stole it. She wanted to throw him over in consequence, and he then "beat her up." After his court martial he said he tried to commit suicide six different ways. In the cells at night he could not sleep "for thinking what a fool he had been," and kept on ruminating about violence and suicide. He was a sturdy individual, with heavily lined facies, co-operative but listless. His depression improved somewhat in hospital, but as soon as he returned to prison he swallowed a foreign body again, necessitating further operation. He lay brooding in hospital, and after trying to strangle himself with a pyjama cord was transferred to a neuropathic hospital.

These are typical examples of this group, and bring out the striking contrast between the two classes of swallower illustrating their past and present instability and their unsatisfactory home lives, and emphasizing the detrimental effect long hours of solitary confinement can have on emotionally unstable prisoners. This would appear also to be the view of such an authority as Norwood East* (It should be added that the long hours of solitary confinement were necessitated by shortage of staff and suitable accommodation and were not favoured by the commandants—though it is also necessary to realize that the problem is complex, as undiluted psychopathy in dormitories is not conducive to peace and quiet).

In contrast to the psychopaths, it is remarkable how completely indifferent some of the stable types were in this respect, nevertheless, with young deserters, some of whose nerve had gone under very severe stress and who were clinically indistinguishable from those who went "down the line" medically, it is very questionable whether solitary confinement is not uneconomical in retar-

rehabilitation as soldiers, which is the aim of military prisons

Finally, these findings would appear to reflect on a small scale the problem of the disposal and reform of the psychopath generally. Clearly law and order must be maintained, but the objection to our present methods is that they so often do not deter the psychopath, while if they result in severe emotional reactions and repeated disturbed behaviour they are not of reformatory value. But, utilitarian reasons apart, punishment causing such a degree of purposeless mental suffering is surely as repugnant as the infliction of physical suffering, which nowadays is contrary to accepted doctrine. Moreover, paradoxically the psychopath, who from the very temperamental defects which drive him into crime tolerates the rigid discipline of prison life less well than the stable criminal, is morally less culpable. For the former often appears genuinely incapable of controlling his impulses, whereas the latter desists from crime

if it does not pay and takes his punishment philosophically if caught. It is to be hoped that the Criminal Reform Bill will grapple with this problem.

Summary and Conclusions

Eleven cases of the swallowing of foreign bodies by prisoners were investigated. 5 only pretended to do so, or swallowed harmless objects, and required two operations between them, 6 swallowed objects and needed 15 major operations in all. The former were stable, the latter emotional and depressed and all 6 were markedly affected by solitary confinement. The swallowing of foreign bodies therefore appears either to be due to very mundane causes or to be caused by severe depression in unstable individuals.

I should like to make acknowledgments to Col G D Gripper, the O.C. of my hospital, and to Lieut Cols Jarret and Mackay, O.C.s of the military prisons concerned, who took great trouble to facilitate my investigation. I also wish to thank Capt Oliver, psychologist to a W.O.S.B. for his help in our abortive attempt to test the prisoners.

SWALLOWED FOREIGN BODIES SOME CASES TREATED IN A MILITARY HOSPITAL

BY

G St J HALLETT, F.R.C.S.

Major, R.A.M.C.

The practice of swallowing foreign bodies as a means of gaining admission to hospital is not uncommon in military prisons. The treatment of these cases presents many problems, both surgical and psychiatric. There are two large detention barracks in the area served by this hospital and 19 individuals have been treated here for the condition. Some have been admitted on several occasions, making a total of 29 admissions.

It is proposed to deal with only the surgical aspect. The cases have been set out in the accompanying Table, from which it will be seen that the outcome has been as follows:

Foreign bodies passed per rectum	20
Operations	12
Gastrotomy	7
Caecostomy	1
Colostomy	1
Laparotomy only	3
Deaths	0

A surprising assortment of objects have passed through the intestinal tract with impunity. These include nails, pieces of glass, spoon handles, pieces of wire, brass buckles, broken razor-blades, and, on one occasion, a needle. They have appeared at intervals of from 48 hours to 12 days after being swallowed.

Table Showing Analysis of Cases

Case No	Date	Object Swallowed	Treatment	Comment
1	4-13/4/45 20/4/45-12/5/45	Collar hook and buttons Numerous F.B.s	No operation Gastrotomy on 22/4/45. 22 metallic F.B.s removed.	Passed per rectum Uneventful recovery
2	25/5/45-6/6/45 6/6/45	2 screws Numerous F.B.s	No operation Gastrotomy 11/6/45	Passed per rectum Uneventful recovery
3	17/4/45-2/5/45 21/4/45-15/5/45 23/5/45-6/6/45 12-29/6/45	Spoon handle Nails etc. Spoon handle and other F.B.s	No operation Gastrotomy 22/4/45. F.B. removed No operation Gastrotomy 18/6/45. Spoon handle removed. Other F.B.s had passed pylorus.	Passed per rectum Uneventful recovery Passed per rectum Uneventful recovery Other F.B.s passed per rectum
4	14-30/11/45	Spoon handle	No operation	On 24/11/45 F.B. still in stomach. Pre-operative radiograph after morphine and hyoscine showed F.B. to have passed pylorus. Ultimately passed per rectum. Transferred to mental hospital.
5	13/6/45-2/7/45	Nails and other small F.B.s	Laparotomy 18/6/45	Nothing palpable in stomach. Abdomen closed without further exploration. F.B.s passed per rectum.
6	8-30/7/45	Thermometer and various bits of wire	Gastrotomy 19/7/45. F.B.s removed	Uneventful recovery
7	10/1/46 17-20/6/45 18-24/6/45 19/6/45-22/9/45	Spoon handle Various small F.B.s Spoon handle 3 pieces of wire	No operation Laparotomy. Removal of wire from pelvic colon. Colostomy 30/6/45	Passed per rectum Progress of F.B. observed by radiographs every 3 days. Wire perforated pelvic colon on 11th day. Uneventful recovery.
8	5-16/7/45	2 spoon handles	Gastrotomy 6/7/45. F.B.s removed	Uneventful recovery
9	20-21/7/45	Pieces of glass	No operation	Passed per rectum after discharge from hospital.
10	7-18/8/45	Open safety pin	Laparotomy 7/8/45. Pin removed from caecum.	Uneventful recovery
11	17-18/9/45 20-25/8/45	Various small metallic F.B.s Spoon handle	No operation	Passed per rectum after discharge from hospital. Pre-operative radiograph after morphine and hyoscine on 25/8/45 showed F.B. to have passed pylorus.
12	24-25/1/46 7-20/11/45	2 spoon handles Spoon handle	Laparotomy. F.B. had passed pylorus. Abdomen closed without further search. Gastrotomy 30/11/45. F.B.s removed.	Passed per rectum Passed per rectum after discharge from hospital. Passed per rectum
13	24/11/45-13/12/45	Toothbrush handle spoon handle and wire	No operation	Uneventful recovery
14	10-17/1/46	Three small metallic F.B.s	No operation	Passed per rectum
15	16-18/1/46	Ring and other small F.B.s	No operation	Passed per rectum after discharge from hospital.
16	16-18/1/46	Spoon handle	No operation	"
17	16-18/1/46	Screws and other small F.B.s	No operation	"
18	19-26/1/46	Sewing needle	Laparotomy 20/1/46. Needle passed pylorus. Abdomen closed without gastrotomy.	Passed per rectum 26/1/46
19	21-23/1/46	Spoon handle and piece of wire	No operation	Passed per rectum after discharge from hospital.

Perforation occurred only in Case 7. On this occasion a piece of wire 3 in (7.5 cm) long became impacted in the pelvic colon for seven days. At operation the wire was found projecting into the peritoneal cavity through a hole in the pelvic colon and there was considerable pelvic peritonitis. The wire was removed, the bowel repaired, and a left iliac colostomy performed. This was later closed, but the man was in hospital for three months. The chances of perforation are evidently not great, nevertheless every effort must be made to avert it. It has been suggested that it is worth swallowing some cotton-wool in the hope that it will entangle a sharp foreign body in a woolly bolus. This was tried on one or two occasions, but with no noticeable effect. Liquid paraffin may safely be given, but it is not advisable, on theoretical grounds, to give any purgatives, as convulsive movements of the bowel might precipitate a perforation.

In some of the earlier cases in this series it was considered, from the size or quantity of objects in the stomach, that they were unlikely to negotiate the intestinal tract without damage, and in these laparotomy was performed. However, in several cases, although the foreign bodies had been shown in pre-operative radiographs, when the abdomen was opened nothing was palpable in the stomach. The abdomen was closed without further exploration, and in all cases the foreign bodies ultimately appeared per rectum. It seems likely that an injection of morphine and hyoscine relaxes the pylorus and helps the stomach to empty. This was given with success in Cases 3 and 11, and it is well worth trying where there is no indication for early operation.

Indications for Operation

1 It is advisable to remove objects which remain in the same position in the bowel for seven or eight days. The mucosa of the stomach which has retained foreign bodies for more than a week is found at operation to be very congested and oedematous. In these circumstances there is clearly a danger of perforation even with blunt objects. So long as there is slow progress operation is not called for. In several cases spoon handles have been passed naturally after 10 to 12 days.

2 Sharp-pointed needles or objects unlikely from their shape to negotiate the intestinal tract are better removed from the stomach, where their location is relatively easy and where the bowel can be most safely opened.

3 If perforation occurs

The routine treatment adopted has been to keep these men under observation on a normal diet and to take radiographs every three days. Operation was undertaken only in the presence of one or other of the indications enumerated above.

I am indebted to Col G D Gripper for permission to publish these cases.

At a meeting of representatives of special hospitals organized for postgraduate teaching held at the Hospital for Sick Children on Feb 11, with Sir Ernest Gowers in the chair, it was unanimously decided to set up a representative body to be known as the Association of Postgraduate Teaching Hospitals of Great Britain. Membership of the association is limited to hospitals or groups of hospitals having directly attached to them institutes federated or about to be federated to the British Postgraduate Medical Federation (University of London) or, in the case of provincial hospitals, institutes recognized and financially supported by a university as postgraduate teaching centres. The objects of the new association were defined as "to keep under review all matters peculiarly affecting the interests of the member hospitals, and to act as a negotiating body directly with the Ministry of Health, universities, local authorities, and other bodies on behalf of those hospitals on such matters as may peculiarly affect them." The acting hon secretary, Mr John Young of the Royal National Throat, Nose and Ear Hospital, Gray's Inn Road, London, W C 1.

VARIATION IN THE TITRE OF Rh ANTIBODY DURING PREGNANCY

BY

M D HICKEY, MD, MSc, MRCPI, DPH

AND

E de VALERA, MD, MAO, MRCPI

(From the Mater Misericordiae Hospital Dublin)

Many published cases indicate that severe erythroblastosis may occur where there is only a comparatively low titre of antibody in the maternal serum—for example, Cases 1, 3, and 6 of a series recently published by Cappell (1946). This author suggests that a rising titre of maternal antibody during pregnancy would indicate the presence of a Rh-positive foetus. He also says that the foetus may be affected without any such rise in titre taking place. In this connexion little attention appears to have been devoted to the possible effect which the continued presence of the foetus might exert on the titre of the maternal antibody by acting as an absorbing agent. For this reason the following case seems worthy of record.

Mrs W, Group O Rh-negative rr. Mr W, Group O, Rh positive R₂R. March 12 1942 Male full-term child, alive and well. Group O Rh positive, R₂r. June 24 1944 Male full term child ieterus gravis died in a few hours. Dec 5, 1944 Uterine bleeding, probably abortion. March 1, 1945 Abortion. Aug 1 1945 Abortion.

Aug 10 1946 Female child caesarean section at 32 weeks. Ieterus gravis. Transfused with Rh negative blood. Died after twelve hours. Group O. Red cells inagglutinable by anti-D serum, presumably due to blocking effect of incomplete anti-D from mother's serum. Weakly agglutinated by rabbit anti-human globulin serum (Coombs *et al*, 1946). Blood films frankly erythroblastic. Baby's serum gave positive blocking test. Antibody was not demonstrated directly by the conglutination method, but when the baby's serum was added to the first tube that showed no agglutination in a titration of the mother's serum by the conglutination method agglutination of Rh₊ cells resulted.

The mother's serum contained a weak antibody, complete anti-D, after the second pregnancy. The titre of this antibody fell after a few weeks. Her serum was first titrated by the conglutination method (Wiener, 1945) before the commencement of the last pregnancy. The titration figures given below suggest that the antibody titre was falling before pregnancy began. A rise occurred early in pregnancy, followed by a fall. This, we suggest, is probably due to the absorption of the antibody by the Rh positive foetus. Pregnancy was terminated when the titre started to rise—that is, about the 32nd week. Delivery was followed by an immediate marked rise in titre.

Date	Titre Complete Anti D	Titre Incomplete Anti D

Captain Dutch Army Veterinary Corps

The following account of a fatal case of melioidosis which occurred in a Dutch ex-P O W in Siam may be of interest

Clinical Notes

A Dutch infantryman, a former P O W, aged 46 was admitted to a combined Indian general hospital in Bangkok, Siam, on Nov 6, 1945, with a complaint of weakness and fever

Previous History—He had been resident in various P O W camps in Siam for just over three years and in Nakom Patom, a town in Siam, for the last three months. On Sept 25 he was admitted to a hospital in Siam with a diagnosis of pneumonia. Next day B T malaria parasites were found in the peripheral blood. The patient responded to treatment with sulphapyridine and combined quinine and mepacrine therapy, and by Oct 10 the temperature was normal. Next day his temperature rose and he complained of fever and pains in the chest especially on the left side. On Oct 17 the white cell count was said to have been normal. Treatment with sulphonamides, penicillin, quinine and mepacrine was tried with no obvious effect, the pyrexia continued, and he was admitted on Nov 6 to the Indian General Hospital.

On admission he was pale, sallow, and undernourished. The tongue was dry and coated. There was no jaundice or any enlargement of the lymphatic glands. A slight tenderness was present over the caecum. The liver and spleen were not enlarged. The heart was within normal limits and the sounds were pure and of moderately good tone. A few rhonchi were audible at the bases of both lungs. There was no paresis of the cranial nerves. The tendon reflexes were diminished. The genito-urinary system was normal.

On Nov 8 the temperature was 102.4° F (39.1° C), pulse 116, and respirations 28. The tongue was moist and clean. There was no jaundice. Small palpable lymphatic glands in axillary and inguinal regions were noted. Abdominal examination disclosed no abnormality. The liver and spleen were not enlarged. The chest was clear and the heart was within normal limits with sounds of poor tone and rhythm grossly irregular (slow fibrillation). On examination of the nervous system the only points of interest were the inability to elicit knee-jerks and abdominal reflexes. The blood pressure was 105/70. The case was suggestive of "subacute bacterial endocarditis". Penicillin therapy was started 40 000 units at once and 20 000 units three-hourly. On Nov 13 the temperature was 103.8° F (39.9° C), pulse 120 and rhythm irregular. A few rhonchi were heard at both lung bases. The heart appeared enlarged to the right side. Pericardial friction sounds were not audible. Penicillin was stopped on Nov 14 and sulphathiazole, 2 g at once and 1 g four hourly, was given.

On Nov 15 the fluoroscopic report was "There is enlargement of the heart shadow, more marked on the right side. The apex beat is not very distinct. The left dome of the diaphragm is normal in shape and movements. The right dome of the diaphragm is not clearly visualized. Appearances suggestive of pericardial effusion." A pericardial puncture revealed no fluid. The pulse was now regular. Later the patient became breathless and there was dullness on percussion at the right base with crepitations. The liver was palpable (one finger). Pericardial puncture revealed no fluid. Penicillin 50 000 units was injected into the pericardial space. The blood pressure on Nov 20 was 90/55. Next day the dullness persisted at the base of the right lung. Moist rales were

heard over the middle and lower lobes of the right lung. On Nov 27 he was given 40 000 units of penicillin three hourly. Dullness at the base of the right lung, ? Grocco's triangle, was present on Nov 30. No fluid present. On Dec 2 the patient was still running a temperature, despite penicillin. The heart was enlarged to the right and left, the spleen was just palpable and the liver was not enlarged. Screening showed a right interlobar collection of fluid. The blood pressure was 90/70. A radiological report of the chest on Dec 6 was as follows: "There is a homogeneous dense shadow involving almost the whole of the right side of the thorax. The right costo-phrenic angle is completely obliterated. Fluid present." On the 7th the chest was explored and 10 ml of straw coloured fluid was withdrawn for examination in the laboratory. The chest was again explored on the 9th and 200 ml of straw coloured fluid was withdrawn. On Dec 11 he had diarrhoea, six stools a day, a course of sulphaguanidine was started, but it had no effect on the diarrhoea. A therapeutic emetine course was started on the 14th. The stools contained *Ankylostoma duodenale*. Treatment was not possible because of the patient's poor condition. On Dec 18 he became breathless, there was marked oedema of the feet and legs and ? ascites. The urine was clear "Mersalyl," 2 ml daily until the oedema subsided was prescribed. A generalized petechial rash appeared on the 19th, and the left knee-joint was hot and swollen (suggestive of septic arthritis). He was given penicillin, 40 000 units four-hourly, and sulphathiazole 2 g at once and 1 g four-hourly. Nikethamide was to be given if necessary. The urine contained a few white blood cells and granular casts. On Dec 20 the patient was moribund. The temperature was 97.4° F (36.3° C), pulse 140, and respirations 60. The oedema of the feet and legs and ascites had disappeared. The heart was enlarged to the right and left. The sounds were pure but of poor tone. The rhythm was regular. There was dullness over the base of the right lung posteriorly. Vocal resonance and fremitus were diminished. Breath sounds were not well heard. There were a few rales at the base of the left lung. Abdominal examination revealed no free fluid, but the tip of the spleen was palpable though not tender. The liver was not enlarged. The patient died at 4.40 p.m.

Laboratory Investigations

On Nov 6 the white cells numbered 17 500 per c mm (neutrophil polymorphs 75%, eosinophils 2%, large and small lymphocytes 18%, large mononuclears 5%). The sedimentation rate (Westergren) was 1st hour 105 mm, 2nd hour, 126 mm. On Nov 20 a blood count showed red cells 3 060 000, haemoglobin, 50% (Sahli), white cells 8 000 (neutrophil polymorphs 82%, eosinophils 2%, large and small lymphocytes 16%). On Nov 27 the white cells numbered 11 200 per c mm (neutrophil polymorphs 81%, eosinophils 2%, large and small lymphocytes 14%, large mononuclears 3%). A blood count on Dec 6 showed red cells 3 040 000, haemoglobin 47% (Sahli), white cells 11 800 (neutrophil polymorphs 81%, eosinophils 1%, large and small lymphocytes 16%, large mononuclears 2%). Malaria parasites were not found in peripheral blood smears taken on Nov 9, 10, 13, 14, 24, 30 and Dec 2. Examination of peripheral blood smears for *Spirochaeta recurrentis* was negative on Nov 6. Blood cultures for enteric group and other organisms made on Nov 6, 11, 21 and Dec 19 were sterile after 14 days. The Widal and Weil-Felix tests revealed nothing of significance, and *Brucella abortus* was not found. Examination of urine on Nov 6 and 15 showed albumin nil, sugar nil, deposits, nothing abnormal. On Dec 20 albumin and sugar were not present but there were a few granular casts per field. Culture of midstream urine was sterile on Nov 10 and 12. Faeces culture for the enteric group on Nov 7, 13 and 18 revealed no pathogenic organisms. Examination of faeces for *Entamoeba histolytica* on Nov 7 was negative. On Dec 14 ova of *A. duodenale* were found. The sputum was negative for acid fast bacilli when tested on eight occasions from Dec 8 to Dec 15. Examination of the pleural fluid showed no cells or organisms in direct smear, culture sterile, and guinea-pig inoculation for tubercle bacilli was negative.

Post-mortem Findings

A necropsy was performed (by C R P and A Van de S) on four hours after death with the following results. *Central nervous system* No macroscopical abnormality seen in skull, meninges

r surface of brain. Cut-sections of cerebral hemispheres cerebellum, and brain stem disclosed no lesions. *Respiratory system*. Trachea and bronchi contained some fine frothy fluid. Left pleural cavity dry and contained no adhesions. Right pleural cavity contained about 2 pints (114 l) of straw-coloured fluid. Both lungs were crepitant and on section revealed no lesions. Hilar glands appeared normal. *Cardio-vascular system*. Both layers of the pericardium were firmly adherent completely obliterating the pericardial cavity. Heart normal in size. Myocardium pale and flabby. Valves were competent, and exhibited no lesions. Endocardium appeared normal. *Alimentary system*. Oesophagus, stomach, and duodenum presented no unusual features. Numerous abscesses varying in size, were seen in the wall of the small bowel, at intervals of approximately 6 in (15 cm), from almost the commencement of the jejunum to about 3 ft (90 cm) from the ileo-caecal junction. No lesions were observed in the colon. The spleen was approximately three times enlarged. A cut section disclosed soft dark red pulp. The liver was swollen and pale, cut sections revealed no disturbance of the lobular pattern. The gall bladder contained about 2 oz (57 ml) of clear bile. Nothing abnormal was seen externally and in cut sections of the pancreas. *Urinary system*. Both kidneys were enlarged and contained numerous small abscesses particularly in the cortices. A number of these abscesses had coalesced to form a honeycomb appearance. The suprarenals appeared normal on external examination and in cut sections. Cultures on blood agar were made from heart blood from the spleen, and from the abscesses in the bowel and kidneys. The same organism was isolated in each case.

Bacteriological Findings

(By C R P and A Van de S)

The organism isolated presented the following features. Gram-negative rods approximately $1\ \mu$ in length showing some pleomorphism and bipolarity ("safety pin" appearance). Actively motile. Aerobic. Grew easily on ordinary media. Growth in broth resulted in pellicle formation with a ropy deposit in the depth of the medium and a peculiar aromatic odour. The pellicle became rough and wrinkled after four days. On nutrient agar button-like colonies with flat rims, and central crater-like depressions developed. Growth on 5% glycerin agar was first of the mucoid type but after three days developed the typical corrugated form of *Pfeifferella whitmori* (*Malleomyces pseudomallei*). Fermented lactose, glucose, mannite, dulcitol and saccharose, without gas formation. No indole formed from peptone water.

Animal Inoculation.—An adult male guinea pig inoculated intraperitoneally with 0.1 ml of a faintly opalescent saline suspension of the organism developed the typical "Strauss" reaction after 48 hours and died in four days. A post-mortem examination of the animal revealed both testicles were markedly swollen and inflamed. The tunica vaginalis was oedematous and haemorrhagic, and contained in the sac a small quantity of turbid fluid. Numerous miliary nodules were observed in the liver and spleen in the omentum and on the peritoneal surface of the bowel. Both lungs were congested. One small nodule was seen in the base of the right lung. The organism was recovered in pure culture from the heart blood and from the lesions in the liver and spleen.

Summary

A case of melioidosis diagnosed after death is described. The main clinical features were slow fibrillation, pericarditis with effusion, pleural effusion, diarrhoea, septicaemia as evidenced by the petechial rash and septic arthritis, and embolic nephritis.

It is believed that this is the second case of melioidosis to have been reported from Siam.

We are indebted to the Director of Medical Services, ALFSEA, for permission to publish this case and to Dr J C Cruickshank, of the London School of Hygiene and Tropical Medicine for kindly confirming the organism as *Pfeifferella whitmori*.

Since the completion of this paper one of us (C R P) has seen six other cases of melioidosis—one in Siam (reported on this page) and five in Rangoon. *Pfeifferella whitmori* was isolated post-mortem in two cases and in the other four cases during life, from sputum, urine, and pus from an abscess in the neck.

A CASE OF MELIOIDOSIS PRESENTING AS AN ABSCESS IN THE NECK

BY

C R PECK

Major IMS IIMC, Officer Commanding an Indian Field Laboratory, SEAC

AND

T ZWANENBURG

Lieutenant, Dutch Army Veterinary Corps

The following account of a case of melioidosis is considered worthy of publication.

Case Report

A havildar aged 25 of the Royal Rajput Regiment was admitted to an Indian general hospital (combined) in Bangkok Siam on Feb 2 1946, with a history of a swelling in the midline of the neck just above the suprasternal notch. It started one month before and when first observed by the patient the lesion was a small mass approximately $\frac{1}{4}$ in (8 mm) in diameter to which he paid no particular attention. It grew slowly and appeared to have caused no real discomfort. The swelling now was about $2\frac{1}{2}$ in (63 mm) in diameter, and fluctuant. It was not particularly tender and there was no erythema of the skin over it. There were no constitutional symptoms, fever or glandular enlargements. The general condition of the patient was good. Similar swellings were not observed elsewhere on the body. There were no associated cases in his unit. The patient had been resident in Siam, just outside Bangkok since August 1945. The leucocyte count, both total and differential presented no unusual features.

Progress.—The abscess was incised on Feb 9, and a small quantity of a peculiar tenacious yellowish brown pus evacuated. Microscopical examination of this material revealed 10 to 15 pus cells per field, amorphous debris and scanty Gram-negative rods about $1\ \mu$ in length exhibiting some degree of pleomorphism and bipolarity ("safety pin" appearance). Culture of the pus on blood agar resulted in a pure growth of *Pfeifferella whitmori* (*Malleomyces pseudomallei*) with features and pathogenicity to guinea pigs as described below. Subsequent progress of the patient was slow, healing of the lesion appearing to be considerably delayed in spite of general surgical measures, antiseptic dressings, etc. It was therefore decided to try the effect of an autogenous vaccine from the strain isolated. This was accordingly prepared, at a strength of 500 millions per cmm and sterility proved, in liquid and on solid media and by intraperitoneal inoculation of an adult male guinea pig. The initial dose administered subcutaneously to the patient was 0.1 ml. Subsequent doses were increased by 0.1 ml every four days until a maximum of 1 ml had been reached. No untoward reactions, local or general were experienced. After the first three or four doses the lesion began to show signs of acceleration in the rate of healing and within one month the condition had completely subsided and the patient was discharged from hospital as "recovered" much pleased with the end-result. A sample of blood serum obtained before starting the vaccine course showed agglutinins to a titre of 1:80 against a killed suspension prepared from the organism isolated. Unfortunately owing to our departure from the station and of the patient to his unit contact was lost. His present condition is therefore not known but efforts are being made to trace him. It was our intention to have estimated the agglutinin titre of this patient's serum on completion of the vaccine course but owing to an oversight and to the rush of work at that time this unfortunately was not done.

Bacteriological Findings.—The organism exhibited the following features. Gram-negative rods approximately $1\ \mu$ in length showing some degree of pleomorphism and bipolarity, the latter being particularly well seen in smears from the original pus, and from the peritoneal exudate of an inoculated guinea-pig. Actively motile. Grew well on all ordinary media. Growth in broth resulted in pellicle formation on the surface with a ropy deposit in the depth of the medium and a peculiar aromatic odour. After four days the pellicle became

gh and wrinkled. On nutrient agar button like colonies, with flat rims and central crater-like depressions developed. Growth on 5% glycerin agar was first of the mucoid type but after four days developed the typical corrugated form of *Pfeifferella whitmorei*. Fermented lactose glucose mannite dulcitate and dextrin with production of acid but no gas. Liquefied gelatin. Milk clotted in four days. Indole negative.

Animal Inoculation—An adult male guinea-pig inoculated intraperitoneally with 0.1 ml of a faintly opalescent saline suspension of the organism developed the typical "Strauss" reaction after 36 hours and died in 48 hours. Post-mortem examination of the animal disclosed both testes swollen and haemorrhagic and some turbid fluid in the sac of the tunica vaginalis. Numerous miliary nodules were observed in the spleen, in the omentum, on the peritoneal surface of the bowel, and in the lungs. There was a large amount of free turbid fluid in the peritoneal cavity. The organism was recovered in pure culture from the heart's blood and from the lesions in the spleen.

Penicillin-sensitivity Tests—The organism was found to be insensitive to penicillin in strengths of 5 and 10 units per ml and even to 100 units per ml, using the half-plate, gutter, and agar-plate cup methods.

We are indebted to the Director of Medical Services A L F S E A, for permission to publish this paper, and to Dr J C Cruickshank, of the London School of Hygiene and Tropical Medicine, for kindly confirming the organism as *Pfeifferella whitmorei*.

Medical Memoranda

A Case of Scurvy

At least three points about scurvy require more investigation (1) the part played by lack of vitamin P, (2) the minimum human requirements of vitamin C, and (3) the discrepancy between the anaemia found in severe scurvy and the lack of such anaemia in depleted volunteers. The following case throws some light upon these three points. Only essential details are presented.

CASE REPORT

The patient, a foundry worker aged 55, lived alone in a single room, with cooking appliances limited to a gas ring. He had eaten no potatoes for 30 years, and no green vegetables. He used to eat tinned tomatoes, till the entry of Italy into the war deprived him of his favourite brand. Every morning he had about a pound of oatmeal scalded in water, and with this he took what marmalade he could get (he estimated it as 2 lb (0.91 kg) a week). For the rest of the day he had bread and dripping, with which he consumed his meat ration. He worked hard and felt well until about four weeks before admission, he injured both shins at work. This resulted in extensive bruising of both legs, accompanied by a severe pain which prevented sleep.

On admission to the Royal Infirmary, Sheffield, he exhibited very striking scorbutic phenomena—viz, typical scorbutic gums, purpuric rash on legs and arms, with follicular keratosis and haemorrhage and very extensive bruising and swelling of both legs, worse in the left leg, where it extended from buttock to foot, with a knee joint which was hot and grossly swollen. On March 29, 1946, a blood count showed Hb 42%, R B C, 3,000,000 W B C, 4,800, and serum bilirubin, 2.1 mg per 100 ml. He was euphoric and slightly fatuous. There were, however, no signs of vitamin B deficiency. He was put on a sterilized milk diet, and care was taken to see that no unprescribed ascorbic acid reached him. He was given 20 mg of ascorbic acid daily. On April 3 a definite improvement in the gums was already noticeable and he made an uneventful recovery, apart from an attack of diarrhoea which began when his diet was increased after the fact of recovery was well ascertained. Before leaving hospital he was instructed in regard to his diet and was saturated with ascorbic acid. He was given 600 mg of ascorbic acid daily, and after two days the excretion of 100 mg daily was attained. His haemoglobin had reached 70% by May 20. No haematonic drugs of any kind were given.

CONCLUSIONS

A markedly haemorrhagic form of scurvy can occur in spite of the ingestion of apparently generous quantities of marmalade, and it can be cured without adding vitamin P.

If 20 mg of ascorbic acid daily will cure a very severe case of scurvy it is legitimate to assume that the minimum requirements for health are not more than this possibly less. Hence the prescription of ascorbic acid to people on ordinary diet is a waste of very precious material.

The swelling of the legs was probably largely due to haemorrhage which caused the anaemia. This view is supported by the high bilirubin content of the serum and by the satisfactory recovery without haematonic drugs, the blood being reabsorbed and refashioned.

This method of treatment was undertaken to test the reliability of the conclusions drawn from a recent M R C experiment. Undoubtedly the safest means of treating true scurvy is by immediate saturation with ascorbic acid.

My thanks are due to my clinical assistant Dr C E Davies, my house physician Dr Horne and Sister Taylor for the many observations and the care taken in what was a very responsible experiment.

Recurring Spontaneous Dislocation of the Shoulder-joint treated by an Appliance

The patient, a frail old lady of 83 was first seen by me a year ago. She had been suffering from recurrent dislocations—these sometimes occurring twice a month. The dislocations had to be reduced under an anaesthetic, and the shock and pain were putting her on the down grade.

In view of her advanced age and poor health the drastic operation was considered too risky, so I had built the corset and shoulder 'cup' (C) here illustrated. My corset-maker tells me the style of make and material is broche. I had the corset lifted over the scapula on the affected side, the lift being well over an inch (2.5 cm), as shown in the back view. There is no lift in front. The 'cup' is fitted over the round of the shoulder and is made of a firm webbing. The front view shows the 'cup' attached by a webbing strap which passes across the chest and through a buckle (B), so that the pull on the shoulder can be varied. At the back the 'cup' is attached by a strap to the corset at the middle. It is not buckled. Both these webbings are elastic in nature. This appliance has been in use for 4½ months, during which time the patient has been free from the dislocations.

I am indebted to Mrs Dixon, of Stourport Road, Kidderminster, for her skill and whole-hearted co-operation in the making of this appliance.

ERIC COPLANS M R C S, L R C P
Hon Capt R A M C

Kidderminster

The Rt Hon R A Butler, MP, was elected first president of the newly formed National Association for Mental Health at its inaugural meeting in London on Feb 11. The Duchess of Kent has consented to be Patron, and the Earl of Feversham was elected chairman, Lady Norman, vice chairman, and Sir Otto Niemeyer, honorary treasurer. The Association results from the amalgamation of three leading voluntary mental health bodies: the Central Association for Mental Welfare, the Child Guidance Council, and the National Council for Mental Hygiene, as recommended by the Feversham Committee on Voluntary Mental Health Services. The work of the amalgamated bodies in providing medical, educational, and social services complementary to the Statutory Services will be carried on and greatly extended in close co-operation with the Government and local government authorities concerned. The new association has been entrusted with the organization of the International Congress on Mental Health to be held in London next year.

Reviews

GYNAECOLOGICAL DIAGNOSIS

Lehrbuch der gynäkologischen Diagnostik für Ärzte und Studierende By Prof. Dr. W. Neuweiler (Pp. 474, illustrated, Swiss francs 58.) Berne: Medizinischer Verlag Hans Huber.

Neuweiler's *Textbook of Gynaecological Diagnosis* must, without doubt, be regarded as one of the most important contributions to gynaecological literature in the last twenty years. Neuweiler has been able to condense into some four hundred and fifty pages a description of most of the modern methods of gynaecological investigation and diagnosis. The volume is well illustrated with some excellent photographs.

The modern methods of investigation are described in detail and great stress is placed on hysterosalpingography. The danger of insufflation is emphasized, and Neuweiler maintains that only carbon dioxide should be used. An excellent photograph of the space between the liver and diaphragm after successful insufflation is included. A good account is given of the different types of vaginitis, some of which are not well known in this country. The classification and description of irregular uterine haemorrhage follow the German system, with no mention of chronic subinvolution and little attention paid to chronic metritis. The sections on carcinoma of the uterus are extremely good, with some pertinent illustrations of the metastases. An illustration is given of the histology of psoriasis uteri. Dysmenorrhoea is considered in some detail and by an approach rather different from that in this country. The section on ovarian tumours is of very great value. The most disappointing section is that on sterility, which is too condensed. It is hoped that the book will receive attention from gynaecologists over here, for there is much to be said for being familiar with the Continental method of approach to the practice of gynaecology.

MEDICAL LECTURES FROM PARIS

Clinique et Investigations By Noël Fiessinger (Pp. 831, 192 figures, 750 francs.) Paris: Masson et Cie, 1946.

Hépatites Rares By Maurice Loeper (Pp. 216, 290 francs.) Paris: Masson et Cie, 1946.

The first of these two books is on the relation between clinical medicine and special investigations. The author is a professor of medicine in Paris and well known for his work on the liver and the blood. The subject matter consists of about fifty clinical lectures, grouped in six sections according to the importance of the special investigations in the management of the cases described. The lectures have been chosen to illustrate the varying role played by the laboratory in the management of patients. While diagnosis may often depend entirely on radiological or laboratory data, at other times investigations are merely an aid or a guide in the management of the case, and they may even be misleading. The last two sections of the book give instances where investigations gave no help, either because a purely clinical diagnosis was possible or because diagnostic mistakes occurred in spite of the full use of laboratory methods. The subdivision is, of course, artificial and the classification often arbitrary, and not all the lectures fit easily into the scheme of the book. Conceived in this way the book provides only an incomplete account of the interpretation of laboratory methods, and that not up to date, since many of the lectures were given in 1941.

The general theme is that though laboratory results may be obtained with scientific precision, their application to clinical problems is rarely simple and their value depends entirely on the clinical context. That this fact has not always been appreciated is shown by the changing fashions in application of particular tests and the author gives a good account of the long time it has taken for such tests as the estimation of the blood urea in nephritis or of the blood cholesterol in cholelithiasis to be given their proper significance. Every new discovery in diagnostic methods appears to suffer a period of unwarranted popularity before knowledge of its limitations becomes sufficient to make interpretation safe, and the author believes it takes twenty years to prove the value of a new test. The book is

long, and each lecture includes detailed case reports and often discussions on aetiology, pathology, and treatment. As is common in French writings, theoretical speculation, particularly on pathogenesis, is allowed more scope than seems justified by the evidence, but diagnosis is based on careful observation and logical deduction. The lectures cover a wide variety of diseases, and the selection of topics has depended on the available clinical material, so that rarities such as chloroma are dealt with as fully as gastric ulcer and myocardial infarct. Many common conditions receive no mention. Cirrhosis of the liver and gout are considered in full detail. Two lectures give interesting information on the medical aspects of famine in Paris during the German occupation—that on

Anémies Erythroplasmanques, which includes a study of oedema formation in relation to plasma-protein changes in these patients, and that on hypoglycaemic coma due to starvation. The informal style appropriate to the lecture theatre in which the book is written adds considerably to its length. There is no index, and references are few and mainly to the French literature.

The second book comprises a series of twenty-one clinical lectures by a professor in charge of a medical clinic in Paris. The first five lectures deal with sulphur metabolism, oxaluria, oedema, osteomalacia, and anaemia in disease of the liver. The remainder are entirely clinical, and deal with uncommon topics such as the changes in the liver in tuberculosis or death from haemorrhage into a carcinoma of the liver. The choice of subjects has been determined by the accidents of the clinic and there is no general theme or design. Statements appear to be based on a few cases, and there is no background of collected and analysed material. The few references are to French authors, and there is no index. It is difficult to imagine an English or American professor writing such a book, difficult too to imagine many English speaking people wishing to read it. Clinical medicine, like patriotism, is not enough, and the day of the elegant series of clinical lectures is gone. We may regret the passing of good showmanship in the out-patient department, the charm of eloquence in the lecture-room and the elegant phrase in writing, but as we learn more about disease in animals and man, and as the total number of scientific workers increases, it becomes essential to present our knowledge in a different form. To-day is the day of the monograph and the review.

TREATMENT OF FRACTURES

The Management of Fractures, Dislocations and Sprains By John Albert Key, B.S., M.D., and H. Earle Conwell, M.D. F.A.C.S. Fourth edition (Pp. 1,322, 1,316 illustrations, 63s.) London: Henry Kimpton, 1946.

The third edition of this book was favourably noticed in our columns in August, 1943 (p. 169), comment being made on the revision of the chapter on compound fractures necessitated by the introduction of the sulphonamides. Further revision of this section has now been carried out, and the present edition incorporates this along with what has been learnt from war experience in the treatment of skeletal injuries, vast numbers of all varieties of which were of course provided by the carnage which then took place. As might be expected the principal changes in the book are in sections on the spine and hip and those dealing with compound injuries. One chapter entitled 'First-aid in Fractures and Automobile Injuries' should serve a very useful purpose. Many of these injuries occur at some distance from a hospital, and as a result doctors who do not usually practise surgery may be called upon to render first aid. Unfortunately the Thomas arm and leg splints, so valuable in such accidents, are but rarely available in doctors' surgeries, and so first-aid measures have to be adapted to the available apparatus—usually boards, bandages, cloth and padding—and it is with the use of such materials that this chapter deals. Part II of the book, which covers the diagnosis and treatment of specific injuries, remains one of its most attractive features, and the article on fractures of the spine is particularly well written and illustrated.

This book should continue to be an authoritative and highly practical guide to students and practitioners, and we foresee that the new edition will be as popular as those preceding it. It can confidently be recommended as a comprehensive account of the commoner skeletal injuries and their modern treatment.

and we can write of this edition as we did of the third. We have the highest praise for it and we thoroughly recommend it to surgeons and practitioners everywhere.

OESTROGENS AND PROSTATIC HYPERTROPHY

The Internal Secretion of the Germinal Tissue of the Testes and Prostatic Hypertrophy By Nils Tornblom Uppsala Almqvist and Wiksells Boktryckeri—A—B (Pp 106 Price not stated)

The experimental work here described by Dr Tornblom was noticed in an annotation in the *Journal* (Dec 9, 1944 p 759). The author discusses the hormonal activity of the testes largely, though not solely, from the point of view of prostatic hypertrophy. It will be recalled that according to the earlier hypothesis of Lower a hormone other than testosterone is normally secreted by the testicles. The decrease in its secretion in later years causes an increased secretion of gonadotrophin, just as in the ovarian failure of elderly women. The gonadotrophin, acting on the still functional cells of the testicles, gives rise, according to this hypothesis, to an increased output of testosterone and thus to prostatic enlargement. A second hypothesis is almost the opposite of Lower's. It assumes that in old men the output of testosterone is diminished and that the prostatic enlargement is due to the unopposed action of the oestrogens normally present even in the male.

In an attempt to settle this controversy Tornblom planned and executed the experiments here described. They demonstrate that the germinal epithelium of the prostate produces an oestrogenic hormone which is probably oestradiol. Valuable as this information is, it leaves the original question unanswered. Dr Tornblom uses his experimental results as evidence in favour of Lower's hypothesis but it can easily be seen that they support equally well the contrary proposition. Nevertheless, the book is a clear exposition of a series of valuable experiments beautifully planned and executed.

STANDARDIZATION IN HAEMATOLOGY

Haematological Technique By Drs L. Everard Napier and C. R. Das Gupta. Third edition (Pp 128 Rs 8) Calcutta U. N. Dhur and Sons 1945

This little book contains an account of the routine methods for the investigation of anaemia used at the Calcutta School of Tropical Medicine. The authors stress the advantages of examining venous blood and of recording haemoglobin in grammes per 100 ml. The techniques are well selected and they are fully and clearly described. If they become standard practice throughout India, as the authors hope, haematology there will be accurate and up to date. Whatever the case in other fields of medicine, in haematology accuracy and standardization are preferable to personal choice and variety. The first two editions of this book were rapidly exhausted, and the same will probably be true of the third. In a fourth edition we suggest that something should be said about plasma jaundice and rather more about the Rh factor. Furthermore as the inexperienced are apt to lay too much stress on differences between successive counts or apparent departures from the normal, a chapter might be devoted to the simple statistics of blood counting, indicating the margin of error of the various techniques.

A second edition of Dr E. B. JAMIESON'S *Illustrations of Anatomy for Nurses* has now been published in a new form of binding, which can be opened out flat or folded over completely so as to show any particular plate as a single sheet. It consists of 64 coloured plates, the majority of which have been selected from the author's well known *Illustrations of Regional Anatomy*. Certain changes have been introduced in the way of improvements in the colour-blocks and by the addition of new distinctive coloration—e.g., purple to distinguish the portal from the systemic venous system, which is represented blue. Great pains have been taken also to render the indicating lines distinct, so that their course over a darkly coloured area can easily be followed, and an index of the names employed has been added, so that many of the abbreviations used in the plates can be easily recognized by beginners, and the particular plates in which the objects are named readily found. This new edition will no doubt achieve an even greater popularity than the first and be a great help to nurses who in their study of anatomy have little opportunity of seeing or handling dissected parts. It is published by E. and S. Livingstone of Edinburgh, at 8s. 6d.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Pharmaco Therapeutic Notebook. By H. W. Tomski, M.P.S. (Pp 280 15s.) London: Baillière, Tindall and Cox 1946

A summary of pharmaceuticals intended for pharmacists, medical students and general practitioners.

Stedman's Practical Medical Dictionary By N. B. Taylor, M.D. F.R.S.(C), F.R.C.S.Ed., in collaboration with A. E. Taylor, D.S.O. M.A. Sixteenth edition revised (Pp 1,291 42s.) London: Baillière, Tindall and Cox 1946

The new edition of this well known dictionary contains an etymological section besides many other additions.

1946 Year Book of Eye, Ear, Nose and Throat By L. Bohman, M.D. (The Eye), S. J. Crowe, M.D. (The Ear, Nose, and Throat), with the collaboration of E. W. Hagens, M.D. (Pp 543 \$3.75 or 21s.) London and Chicago: H. K. Lewis and The Year Book Publishers 1947

Covers recent advances in ophthalmology and the ENT specialty.

The Doctor and Tomorrow By Arthur E. Brown, M.B., B.Ch., F.R.C.S. (Pp 136 3s.) Sydney: F. H. Johnston 1946

The author discusses the future of medical practice in Australia, with particular reference to giving the whole population an adequate medical service.

Recent Advances in Clinical Pathology By various authors. Editor S. C. Dyke, D.M., F.R.C.P. (Pp 468 25s.) London: Churchill 1947

This book covers recent additions to the practice of clinical pathology in Great Britain.

A Textbook of Midwifery By Wilfred Shaw, M.D., F.R.C.S., F.R.C.O.G. Second edition (Pp 649 21s.) London: Churchill 1947

To this edition has been added new work on the Rh factor and erythroblastosis and on chemotherapy.

The Psychoanalytic Theory of Neurosis By Otto Fenichel, M.D. (Pp 703 35s.) London: Kegan Paul, Trench, Trubner 1946

The author claims to present the psychoanalytic doctrines in a systematic and comprehensive manner. Part I includes an account of medical development, Part II that of the psychoanalytic theory of neurosis.

Mothercraft in the Tropics By K. Macpherson (Pp 205 6s.) London: Cassell 1947

Instruction on the problems of mothercraft and minor ailments in childhood for those living in the Tropics, for the hymen.

The Acute Infectious Fevers By A. Joe, D.S.C. M.D., F.R.C.P.Ed., D.P.H., D.T.M.&H. (Pp 276 18s.) London: Churchill 1947

An introduction to the subject for students and medical practitioners.

Die Hormonversorgung des Foetus By J. Samuels (Pp 320 No price.) Leiden: Brill 1947

An account of the ovarian and gonadotrophic hormones in pregnancy. Written in German with a summary in English.

Materia Medica for Nurses By W. Gordon Sears, M.D., M.R.C.P. 2nd ed. (Pp 246 5s.) London: Edward Arnold 1947

Includes besides materia medica accounts of toxic effects of drugs, the use of hormones, vaccines, and vitamins, and tables of doses.

Pellagra in the Oto Neurology and Rhino Laryngology By Otto L. E. De Raadt, M.D. (Pp 172 No price.) Leiden: University Press 1947

Based on experience acquired when a prisoner of war of the Japanese. In English.

Human Genetics Vols 1 and 2. By R. R. Gates, D.Sc., Ph.D., F.R.S. (Pp 742 and 1,518 £5 for 2 vols.) New York: Macmillan 1946

The author's previous work is gathered together in these volumes and much new material added. Intended as a source book for all concerned with the genetic aspects of medicine or anthropology.

BRITISH MEDICAL JOURNAL

SATURDAY MARCH 15 1947

PRESSURE AT THE CERVICO-BRACHIAL
OUTLET

It is probably fair to say that the causes of backache with or without pain radiating along the course of the sciatic nerve can nowadays be determined with reasonable accuracy. This is not to say that the problem of deciding what in every case is the best remedy has by any means been solved, particularly when the lumbago-sciatica syndrome is due to a lesion of an intervertebral disk. Nevertheless a very great measure of agreement has been reached about the pathology and the treatment of this type of pain in the lower limb. There is still widespread controversy, however, about the causes and the methods of treatment of pain in the upper limb. At one time a cervical rib, or its equivalent, helped by aberrations in the derivation of the brachial plexus was the sole explanation. If no rib or enlarged seventh cervical transverse process was present few surgeons had sufficient courage or conviction to explore the posterior triangle of the neck in search of a fibrous band over which the brachial plexus and perhaps the subclavian artery might be stretched. The unfortunate patient had usually to resign himself to a vague and unsatisfactory diagnosis of neuritis, neurosis, malingering, or fibrositis. The diagnosis of "fibrositis" often had the most serious consequences for the patient. It initiated a regime of treatment beginning with the ruthless eradication of "septic foci," as often as not more imaginary than real, and proceeding through all the currently fashionable forms of physical treatment.

Pain in the upper limb has increasingly affected middle-aged and elderly women during and since the war. Cervical ribs could not be the only explanation if for no other reason than that the syndrome of pain in the shoulder radiating down to the hand is common while cervical ribs are rare. Attention has been concentrated on the possible causes of pressure on the brachial plexus or its roots other than from an accessory rib. Just as our knowledge about sciatica has been increased by anatomical and pathological studies of the lumbar intervertebral disks, so also has "brachial neuritis" been illuminated by similar studies of the cervical disks and the intervertebral foramina.¹⁻³ Diminution in the calibre of a foramen by a prolapsed disk, by osteophytes, or by recurrent subluxation of one vertebra on another, is quite often accompanied by pressure on the corresponding nerve root. Gross involvement of a root, usually the seventh or the sixth, is easily recognized, but minor degrees give rise to symptoms not so readily distinguishable from those caused by pressure on or stretching of the brachial plexus.

Once clear of the spinal column, the nerves have to run further hazards in their journey to the axilla. For most of the way they are accompanied closely if not intimately by the main vessels to the limb so that the clinical picture to which pressure gives rise may be a mixture of neurological and vascular signs and symptoms. The circulatory changes vary greatly in degree. Most commonly the whole hand tingles or goes to sleep, it feels numb or cold to the touch, and it appears blue or pale in colour. At the other end of the scale there is obliteration of the radial, ulnar, and part of the brachial pulse with gangrene of one or more fingers. The risks to which the neuro-vascular bundle is subjected are those of pressure, stretching, and friction. Complaints of tingling, burning pain, and numbness and coldness in the fingers are nowadays common among middle-aged and elderly women. There seems little doubt that fatigue, unaccustomed manual work, and the many hours spent in carrying shopping baskets result in atony of the shoulder girdle, drooping of the shoulder, and stretching of the plexus over the first rib or the anterior edge of the scalenus medius. It has been well known for years that rest followed by graduated exercises to restore the tone and power of the shoulder girdle muscles will often relieve symptoms even when a cervical rib is present.

Anatomical variations in the pathway of the vessels and nerves are an obvious source of pressure or stretching effects. This pathway—the cervico-brachial outlet or tunnel—can be altered in shape and in capacity by a number of factors. It is continually altering with movements of the shoulder and arm. Accessory ribs may be present—the classical cervical rib first noted by Galen and later by Vesalius and so admirably described in the present century by the anatomists Wingate Todd, Wood Jones, and Stopford, and by surgeons, notably Sargent and Telford.⁴ The floor of the cervico-brachial tunnel is formed by the upper thoracic outlet, which may be asymmetrical, tilted, and higher than normal because of lateral curvatures of the spine or because of maldevelopment of the first rib, varying from rudimentary forms to alterations in the shape and curve of the so-called normal. The potentialities for the exercise of a stretching effect are thus numerous. It is also claimed that these structural anomalies of the upper thoracic outlet cause narrowing of the space between the clavicle and the first rib so that the neuro-vascular bundle can be nipped between the two bones when the limb is in certain positions.⁸⁻¹⁰

The anterior and the medial scalene muscles play a part in the production of this syndrome. It may well be that more than these two are concerned. The firm and rather sharp anterior border of the scalenus medius is a ridge over which the plexus can be stretched, particularly if the muscle attachment is carried unusually far forward on the first rib. The scalenus anticus forms an angle with the first rib—the costo scalene triangle in which lie the subclavian artery and the lower components of the brachial plexus. Because of spasm and subsequent hypertrophy the spastic thickened anterior scalene narrows the costo-scalene

¹ *J Bone Jt Surg* 1932 14 877² *Sth med J* 1942 35 663³ *Ann Surg* 1937 106 428⁴ *J Amer med Ass* 1943 121 1209⁵ *Surg Gynec Obstet* 1944 78 350⁶ *Proc roy Soc Med (Clin Sect)* 1913 6 117 *Brain*, 1921, 44 95⁷ *Brit J Surg* 1919 7 168 1931, 18 557⁸ *Lancet* 1943 2, 539⁹ *Clin Sci* 1934 1 327¹⁰ *Brain* 1944 67, 141

gle and thus compresses its contents against the first rib¹¹⁻¹³. How spasm of a single muscle arises in patients in whom fatigue and general muscular atony are otherwise outstanding features is not very clear. The suggestion is made that any painful condition in the area supplied by the fourth, fifth, sixth, and seventh cervical nerves, which also supply the scalenus anticus, may initiate a reflex spasm. Walshe¹⁰ and his co-workers stress the importance of wear and tear of the soft tissues in the cervico-brachial tunnel. They point out that the unceasing respiratory movement of the thorax and the frequent arm and shoulder movements of everyday life cannot but aggravate existing maladjustments between arteries, nerves, and bones. This oft-repeated friction, stretching, and compression of soft tissues may lead to considerable reactionary tissue change. Thus the walls of the subclavian artery may become worn, and the artery may be bound to the first rib by scar tissue, which can also drag on the nearby stellate ganglion, already tethered to the artery by the annulus of Vieussens, thus perhaps explaining the sympathetic phenomena occasionally encountered.

These various conceptions of the hazards which determine stretching, pressure, or friction effects on the neuro-vascular bundle may be summarized briefly as physiological (muscle atony and drooping shoulder), anatomical (anomalies of bone and muscle attachments), and pathological (reactionary soft tissue changes). While it is not difficult to understand how the nerve trunks are usually involved the mechanism of involvement of the main vessel to the limb is by no means clear. At first it was thought that the circulatory disturbances were caused by stretching or kinking of the subclavian artery over the abnormal rib, or by thrombosis within the artery, or by a combination of these factors.¹⁴ Later Todd, Telford, and Stopford claimed that all the vascular changes could be explained by pressure or friction on the sympathetic fibres which enter the arm in the lowest trunk of the plexus and which are occasionally situated in that part of the trunk in contact with the rib. These fibres are distributed to the peripheral vessels at various levels. Irritation of them, as by friction on a rib, induces spasm of the arterial wall, obliteration of the vasa vasorum, and eventually such changes in the health of the vessel wall as to lead to thrombosis and occlusion. In support of this hypothesis is the clinical observation that thrombosis does not extend higher than the level of the pectoralis major tendon, the axillary and subclavian arteries being innervated by a periarterial plexus not subjected to friction and not, like the brachial, radial, and ulnar arteries, by branches from the cerebrospinal nerves.

These views have been severely criticized by Lewis and Pickering in 1934,⁹ by Falconer and Weddell in 1943,⁸ and more recently by Walshe¹⁰ on the grounds that the anatomy of the sympathetic supply to the upper extremity is not as described by Todd, Telford, and Stopford, that long-standing irritation of sympathetic fibres should, as happens in somatic nerves subjected to similar trauma, lead to structural impairment and paralysis with vasodilation, increased warmth and redness of the limb, and loss of

sweating, and that, even assuming a particular topographical arrangement of the sympathetic fibres, it is difficult to understand how recurrent pressure over long periods can disturb sympathetic fibres only in some cases and somatic fibres only in others. These writers suggest that momentary obliteration of the artery in certain movements of the shoulder would account for these so called vaso-motor symptoms and would explain also their momentary duration and their fluctuation. The artery is thought to be nipped between the clavicle and the abnormal rib. Constant repetition of this nipping damages the vessel wall and results in dilation, aneurysm, thrombosis, and periarterial fibrosis. Costoclavicular compression is thus held to account for many of the pressure effects associated with cervical, rudimentary, and even normal first ribs in relation to both nerves and vessels. It is considered the cause of obliteration of the pulse when traction is exerted on the dependent arm and when the arm is elevated. Evidence to support its occurrence has been adduced from venograms, and it has been seen to occur at operation.

The conception of costoclavicular compression as a common cause of either nervous or vascular pressure effects is powerfully challenged by Telford and Mottershead elsewhere in this issue in an article (p. 325) which is a model of careful, painstaking, and patient observation. They base their views on the findings at 120 operations for the relief of pressure on the neuro-vascular bundle of the arm, on the effects of posture of the arm and shoulder girdle on the radial pulse in 120 medical students, and on the evidence obtained by the dissection of 30 cadavers. The characteristic thoroughness of observation at this large series of operations (in only five of which no adequate cause was found) and the careful examination of controls both living and dead give great weight to their conclusions. Telford and Mottershead agree that in a small proportion of cases the clavicle can compress the neuro-vascular bundle against the scalenus medius or an accessory or abnormal rib, but only with the shoulder forcibly retracted backwards or the arm fully elevated. In other positions they regard the idea of costoclavicular compression as "pure supposition unsupported by any anatomical evidence." Depression of the shoulder by traction on the dependent arm may obliterate the radial artery, but it does not obliterate the first stage of the axillary artery. It is clear then that the clavicle is not the compressing agent. The point is further made that when the shoulder is depressed the clavicle moves downwards and forwards so that the costoclavicular space is widened, not narrowed. The compression occurs distal to the clavicle and is considered to be due to an anatomical disposition of the axillary artery in some individuals—perhaps a majority—which allows it to be squeezed between the lateral and medial heads of the median nerve when the shoulder is depressed. Symptoms referable to the plexus with the arm in this position are caused by stretching of the plexus over an accessory rib, an abnormal first rib, or the anterior edge of the scalenus medius. The lack of reference to the scalenus anticus is of interest in view of the fact that it has often been regarded as a causal agent in America and at one time in this country.

This paper marks another welcome step forward in the elucidation of causes of pressure at the cervico-brachial outlet. The authors emphasize, as indeed do nearly all recent writers, that no one mechanical cause can explain all cases. It is possible moreover that there are a number of factors responsible in every case. Obviously, therefore, no one method of treatment, and particularly no one operation, is applicable to all patients. If the symptoms do not settle with rest and simple conservative measures and remain sufficiently disabling, operation is justifiable. There is much to be said for an exploration as thorough as Telford's so that the precise cause of the pressure on nerve or artery can be seen and dealt with appropriately. In this way disappointments from operations applied as a routine to all patients would be avoided. Division of the anterior scalene is a temptingly easy procedure. But the results of this operation are almost as uncertain as the aetiological role ascribed to this muscle. Furthermore, adequate exposure and careful demonstration of the site of the pressure might prove it often unnecessary to do more than divide part of the medial scalene, which is a formidable enough operation, rather than resect part of the first rib.

The briefest survey of the literature reveals the complexity of the problem and the variety of factors responsible for pain radiating down the arm from the neck and shoulder. Nowadays it should be possible to decide before treatment whether the site of nerve constriction is within or without the spinal column. It is perhaps wise to stress the need for careful clinical examination and for comprehensive radiography of the cervical spine and shoulder girdle. It may well be that venograms will prove an increasing help. Much remains to be solved, particularly about the aetiology of vascular thrombosis and the mode of involvement of the sympathetic nervous system, on neither of which points is much said in this paper. It is to be hoped that Prof. Telford and his co-workers will be able to throw further light on these still dark corners of a subject which he and his Manchester colleagues have done so much to illuminate now and in the past.

WATER AND SALT DEPLETION

Ninety years ago it seemed certain that Virchow's doctrines had driven the last nails into the coffin of humoral pathology. The cell was the unit, and in cellular changes, revealed by the microscope, all the secrets of disease were held to repose. Physiologists, led by Claude Bernard, were the first to appreciate again, and in a more precise sense, the importance of the fluids which bathe the cells. With the growth of biochemistry a new humoral pathology has arisen, in which water, the electrolytes, and the plasma proteins have replaced the four humours. In H. L. Marriott's Croonian Lectures, the third of which is published in this number of the *Journal*, this new humoral pathology is expounded with a welcome lucidity. It is remarkable that the metabolism of water, which constitutes 70% by weight of the human body, should have been so long neglected. It is only of recent years that its importance has come to be appreciated in clinical medicine, "dehydration" has now become a popular term, and its alleviation is pursued with

an enthusiasm not always illuminated by a knowledge of the subject's complexities.

The body's water is distributed between two great compartments—the intracellular and the extracellular. The last includes both that within the vessels and that in the tissue interstices. Between these two compartments osmotic equilibrium is maintained chiefly by the electrolytes. Within the cells, potassium and phosphate are the most important ions, without, sodium and chlorine. Although water can diffuse freely through the cell membrane, it is impermeable to the electrolyte ions. Dehydration may be either cellular or extracellular. The first arises when the body is depleted of water without loss of electrolytes: the osmotic pressure of the extracellular fluid rises and water passes out from the cells until equilibrium is restored. In the second, loss of extracellular electrolytes diminishes the tonicity of the fluid in this compartment, renal excretion of water proceeds until osmotic balance is again approached, reducing in consequence the total volume of extracellular fluid. Marriott prefers to speak of the first as "pure water depletion," and the second as "pure salt depletion"; he has stressed the immense importance to the clinician of the distinction between the two. Cellular dehydration follows deprivation of water, either because it is not available, or because it cannot be swallowed, or because physical weakness is so extreme that the patient is incapable of slaking his thirst. Its development may be accelerated by defective renal function necessitating the excretion of a dilute urine. Extracellular dehydration is the consequence of the increased loss of sodium chloride in a patient whose intake of water is sufficient to compensate for that transporting the lost salt. Such losses are the result of the removal or expulsion of what Burton called "excrementitious humours of the third concoction"—sweat, saliva, gastric juice, bile, and pancreatic and intestinal juices. Sweating, vomiting, and diarrhoea account for most cases, but "removal" is added advisedly, for the gastric suction so frequently employed after abdominal surgery can lead to rapid depletion. For pure extracellular dehydration to occur the lost water must be replaced. In cellular dehydration thirst and oliguria are the clinical features; the urine contains normal or increased quantities of sodium chloride. In extracellular dehydration the clinical picture is more complex. There is no thirst, the urinary volume is normal, but, except in Addison's disease, sodium chloride is absent, cramps are common, and such accompaniments of a reduced plasma volume as syncopal attacks, hypotension, and haemoconcentration make their appearance early and progress until peripheral circulatory failure closes the scene. Cellular and extracellular dehydration may occur separately, but it is by no means rare for them to be combined in the same patient.

There is substance in Marriott's criticism of the term dehydration, and good reason for using, as he suggests, labels denoting the underlying causes. But in these new terms there is some danger, perhaps, of these states acquiring the dignified status of "syndromes." It cannot be too greatly stressed that they are dynamic perturbations of the body's chemistry which may arise not only in the simple conditions cited but in circumstances of far greater complexity. The appreciation of the events which may lead to

It and water depletion is as important as the ability to recognize the developed disturbances, because in many instances preventive treatment can and should eliminate their occurrence. In this country the problems are more difficult than in the Tropics, where profuse sweating and choleraic diarrhoea are such obvious causes. In temperate climates water and salt depletion appear frequently during the course of disease-processes which may themselves seem to offer sufficient reason for the patient's deterioration. Their detection in these circumstances will tax the most careful clinician. The fundamentals of treatment are simple: to replace water where water is needed, and salt, where salt. The quantitative aspects are more difficult but none the less important, on this subject, and on the routes by which fluid may be administered, Marriott gives much sound and practical advice. It is to be hoped that his admirable lectures will help to convince those physicians and surgeons who still require convincing that the day-to-day problems of water and salt metabolism are of such importance to their patients that their management should not be left in the hands of house officers and nurses.

MELIOIDOSIS

Melioidosis is a disease which is almost always fatal and is seldom correctly diagnosed during life. Two cases in Allied soldiers in the Far East are described in this issue by Paton, Peck, and Van de Schaaf (p. 336) and by Peck and Zwanenburg (p. 337). Melioidosis,¹ which was first described in 1912 by Whitmore and Krishnaswami² in Rangoon, was later recognized in Kuala Lumpur as an epizootic disease of small laboratory animals by Stanton. The occurrence of human cases in the Federated Malay States, the isolation and further description of Whitmore's bacillus, and the reproduction of the disease in laboratory animals were detailed in the classical monograph by Stanton and Fletcher in 1917.

As its name indicates, the manifestations of melioidosis frequently resemble those of glanders, which is caused by a closely related organism. The disease, observed most often in adult males, may take an acute, subacute, or chronic form and may closely simulate other conditions. The acute form, in which vomiting, collapse, and purging may be followed by death within seventy-two hours, may be mistaken for cholera. The subacute and chronic types take the form of a more or less prolonged febrile illness associated with the formation of multiple abscesses which may be found in almost every organ except the brain, but particularly in the lungs, spleen, and liver. These forms may be mistaken for plague, malaria, enteric fever, pneumonia, amoebic abscess, bacterial endocarditis, or military tuberculosis. A diagnosis of smallpox has been made in cases showing cutaneous vesicles and pustules. Death is likely to ensue in a few weeks or months, but some recoveries are reported, usually in cases with solitary or accessible abscesses.

The essential lesion of melioidosis is a small area of focal necrosis which develops into an abscess, subsequently tending to coalesce with its neighbours to form a honey-combed lesion containing tenacious creamy or, in the liver, glairy greenish pus. Diagnosis is made bacteriologically, by culture of the causative organism from the blood in the early stages, from the pus of abscesses or pustules, from material obtained by splenic puncture, and occasionally from urine, sputum, or cerebrospinal fluid. *Pfeifferella whitmori*, a small Gram-negative bacillus with marked

bipolar staining grows readily on ordinary culture media in a characteristic mucoid or rugose form—so readily that it has probably sometimes been regarded as a contaminant. It produces a brownish honey-like growth on potato and ferments a number of carbohydrates with the formation of acid only. It differs from the glanders bacillus in being motile and in liquefying gelatin rapidly. Final identification may be made by inoculation of the organism into the guinea-pig which dies rapidly with abscesses in the spleen, liver, and lungs. Intraperitoneal inoculation in the male guinea-pig produces the Straus reaction—acute suppurative inflammation of the tunica vaginalis.

Although melioidosis is usually regarded as a rare disease, Stanton and Fletcher³ estimated that it was responsible for at least 200 deaths annually in the Federated Malay States. It also appears in Burma, China, Indo-China, the Netherlands Indies, and Siam. Cases have been reported from Ceylon, Celebes, South Africa, and recently, by Mirick and his co-workers,⁴ from Guam. Melioidosis occurs naturally in rats and more rarely in other animals, and, although Blanc and Baltazard^{5, 7} have suggested that the rat flea or the mosquito might transmit the disease, it seems likely that man acquires the infection by the ingestion of food contaminated by rats. *Pfeifferella whitmori* is not sensitive to penicillin *in vitro* but Mirick and his colleagues found their strains susceptible to sulphadiazine and consider that this or some related sulphonamide is worthy of clinical trial.

NURSING CAMPAIGN

Although more nurses are being employed now than before the war, there is a shortage. The Gloucestershire scheme of part-time service planned by Mr W. A. Shee, public assistance officer to the county council, has been successful in meeting this difficulty. Part-time schemes have been tried before without success, but there is evidence that the chief deterrent is not so much the work itself as the conditions under which it is performed, as Miss Armstrong suggests in an article on page 345 of this issue. The campaign for part-time nurses and midwives in Greater London launched in the Press and on the wireless by the Ministry of Health on Feb. 15 emphasizes the need for providing good welfare facilities, free meals on duty, and free facilities for laundering of uniform and, in certain circumstances, for travelling.

The Ministry has opened reception centres at the Paddington Hospital, St. Mary's (Islington) Hospital, Hackney Hospital, Dulwich Hospital, St. James's Hospital (Balham), and the L.C.C. Recruitment Centre (County Hall). In addition volunteers may apply to their nearest resettlement advice office. Voluntary hospitals are invited to participate. A clearing-house at the Nursing Appointments Office, 23, Portman Square, W.1 (Tel. Welbeck 4486), co-ordinates with vacancies applicants who cannot immediately be placed.

Over 1,400 applicants in London have now volunteered to serve, and doubtless there would have been more if the severe weather had not restricted many people's activities to maintaining a coherent daily existence. If the response that has solved Gloucestershire's nursing problems can be induced in the rest of the country the closed wards and hospitals will be reopened and adequate nursing be provided at last for the chronic and aged sick. Further, the partially trained nurse, or the nurse who has completed her training but given up her career in favour of marriage, so far from being dismissed as "wastage," as at present, will be welcomed as a valuable ally.

THE PART-TIME NURSE

BY

KATHARINE F ARMSTRONG, SRN, SCM
DN (Lond)*Editor of the Nursing Times*

The Gloucestershire scheme of part time nurses, organized by Mr W A Shee, public assistance officer to the county, has completely altered the position of the Gloucestershire public assistance institutions as regards nursing staff. Begun about a year ago, when the shortage of nurses to care for long term patients was so acute that it seemed that wards and even whole institutions would have to close, the county now has 301 part-time "nurses" and a waiting list of those willing to help in this important work at some institutions. It has even been able to staff completely a similar infirmary for a neighbouring county at short notice. At a time when the whole system of caring for the aged and infirm seemed in danger of breaking down these results deserve close study by all authorities faced with similar problems.

Actually the Gloucestershire "part time nurses" are not all nurses in the present sense of the term, as defined by the Nurses Act, 1943. They are graded into State-registered nurses who serve as ward sisters or staff nurses, enrolled assistant nurses, nursing attendants, and nursing orderlies. All are engaged in nursing duties, the nursing orderlies being untrained women who are taught elementary nursing at the bed side and after at least six months' satisfactory work are promoted to the rank of nursing attendants. This training is of the type that many members of the nursing profession envisaged for the assistant nurse when the Nurses Act 1943, was passed.

Success of Scheme

The most interesting point about the plan is that the matrons, although dubious at first of its success and fearful lest the part-time workers should fail to arrive, find that it has, in fact, brought a fine type of woman into their nursing service, it has provided a much better standard of nursing care than they could obtain by the employment of full-time nurses supplemented by temporary help from nursing co-operations, which was some times of a very inferior quality. The patients are happy and obviously well nursed. The scheme has produced one particularly interesting result. Out of the 301 "nurses" 72, or 24%, are State-registered nurses who have come forward to help in this emergency and are enjoying the opportunity of practising their art. What hospitals, acute or long stay, can boast a 24% ratio of fully trained personnel in their nursing staff? Further, the nurses are happy looking after these long term cases—many of them heavy cases and not a few incontinent. The authorities have always thrown the blame on trained nurses for their failure to help in this important branch of nursing work which often requires all the ingenuity and skill of the qualified woman. Of course this experiment is young as yet, though it has successfully weathered a full year so that the effect of novelty may be expected to have worn thin. Does it not, therefore, appear that the fault was rather in the conditions under which nurses were expected to carry out the work, and that perhaps the accommodation provided for them was the deterrent rather than the nature of the nursing work?

The answer may lie in the hours worked, as Dr T B H Haslett consultant physician and pathologist to the Gloucestershire County Council suggested at the conference held in Cheltenham in February to make the scheme more widely known. The part-time workers give what time they can spare, and many work only for a four hour shift daily. The hours are 8 a.m. to 12 noon, 12 noon to 4 p.m. and 4 p.m. to 8 p.m. during the day with a 12 hour night duty from 8 p.m. to 8 a.m. Dr Haslett remarked that this meant that the individual part-time nurse probably had to change each incontinent patient once only a day whereas the full-time staff would have had to do it several times and this tended to be demoralizing. This ought not to be the case, for it is the patient's misfortune and not his fault, and, to the best nurses, sympathy for his plight

and the need to help him to overcome his own distaste for life under these conditions completely oust all feeling of the disagreeable aspect of the work. It is queer how little the average doctor appears to understand this, though he must approach mental and other less pleasant forms of disease in the same spirit if he is to be a first-class surgeon or physician.

Benefits of Rearrangement

The implementation of the scheme has meant a certain amount of reorganization, which also has its advantages. The greatest of these is that the patients are now not disturbed till 7 a.m.—a fact which they greatly appreciate. This is presumably, the result of the fact that the part-time worker who has to travel to her work does not arrive until 8 a.m., and therefore the bulk of the morning routine ward work—washing, bed-making and giving breakfasts—begins at a later hour. Every nurse realizes that her patients would appreciate being awakened less early. For those older patients, who may spend the rest of their lives in an infirmary ward, possibly a period of ten to twenty years, it is particularly beneficial. Dr Haslett asserted that the rearrangement has not "interfered with the work of that non celestial being" the doctor. This is interesting in view of the fact that a surgical ward for carcinomatous cases had been opened at the Cheltenham Infirmary to relieve the waiting list at the general hospital. The problem of waiting for the dust to settle after bed making and sweeping before beginning purifications and dressings has been satisfactorily solved. If the general hospital of the future is to depend at all on part-time nursing this emphasizes the desirability of building new hospitals with a surgical dressing-room, into which beds and trolleys can be wheeled, as a part of every surgical ward unit. Certainly all patients would benefit from any scheme in which the ward day began at a later hour.

The scheme can succeed only if the part-time staff proves reliable. Very naturally matrons always fear this experiment, lest they be left without the essential staff to nurse the patients. There is greater risk of absenteeism, but the extent of it will be lessened if the part time worker is made to feel that she is welcome, is an integral part of the staff and has definite responsibilities. There are divided loyalties, of course. 86.5% of the Gloucestershire part-time nurses are married women with family responsibilities or women living at home with family ties. If there is illness of children or husband the part-time nurse can not carry out her obligations to the hospital, and a sufficient floating staff is essential to meet such occasions without disruption of the nursing service. Any hospital short of full-time nurses will still be better off with part-time assistance and adequate relief arrangements, than it was before. In illness too, it may well be longer before the part-time nurse can return to her work if it means a journey, perhaps in bad weather, in addition to the hours on duty. Suitable allowances must be made for these factors. In Gloucestershire the matrons have found the part-time staff reliable. They have not found that they expected the full-time workers to take all the less desirable periods of nursing service—at week-ends and holiday periods. In one infirmary in fact, the part-time workers volunteered to come in on Boxing Day and relieve the full-time staff entirely, in spite of their outside ties.

Salary Scales

One difficulty with regard to the part time scheme lies in the question of payment and it must be squarely faced. The Gloucestershire scheme began before the Rushcliffe Committee considered the matter and the scales offered were 2s 6d per hour for a State-registered nurse, 2s per hour for an enrolled assistant nurse, 1s 9d per hour for a nursing attendant and 1s 6d per hour for a nursing orderly for those who worked for less than 24 hours per week. Those working longer hours received a proportion of the Rushcliffe scales. The scale for the State-registered nurse is very low for a skilled woman with a three- or four year training behind her. It is however definitely higher proportionately than the salaries of the full time worker in the case of the staff nurse though lower in the case of the ward sister. Nevertheless it has elicited a satisfactory response, and neither the full time nor the part-time workers appear discontented. The Rushcliffe Committee has, however, now issued

a salary scale for the nursing ranks, and it is as follows: 2s 10d per hour for the ward sister, 2s 1d for the State-registered nurse and 2s for the enrolled assistant nurse. These figures the committee reached by taking the average salary for the rank—i.e., the salary after five years' service—and allowing an additional 12½% loading because the part-time worker had no pension rights and no security of tenure. The figures serve to reveal how low the basic salary scales still are, though they show nursing salaries in an unfortunate light to the layman because of the under-valuation of the nurses' emoluments. For these calculations the nurses' board, lodging, laundry, service, and medical care are valued at £100 per year for the staff nurse and £120 a year for a ward sister. Most part-time nurses will probably be in the staff nurse category. It is quite impossible, certainly in London, to obtain bed and breakfast for less than £2 per week, excluding other meals, personal laundry, and service. The part-time worker lives out in a world where prices are greatly increased. She may have to obtain reliable domestic help to enable her to leave home at all, it will probably cost her at least 2s per hour and be difficult to find.

The full-time worker should not therefore grudge the part-time worker a higher salary scale than that which the Rushcliffe Committee suggests. She has the benefit of her pension rights, her security of employment, her holidays with pay, and opportunities for promotion. She may not appreciate these advantages fully to day, but she will later. She should do all in her power to attract the part-time nurse and work for improvement in her salary scale as well as in the scale for the full-time workers in the nursing services. Part-time nurses have already volunteered to help in London, and in other counties where similar appeals are being made, in quite good numbers. So long as there is a shortage of full-time workers—and this may well be permanent—they will be needed, unless beds are to be limited. In London the total is about 1,000 helpers within three weeks, and 173 of them are State-registered nurses. In Gloucester the part-time nurses have themselves proved the best advertisement for the scheme and brought in many others. There is no reason why this should not be so elsewhere and prove a permanent factor in meeting the nursing shortage.

WELFARE OF DISABLED IN SCOTLAND

In November, 1946, the number on the Disabled Persons Register in Scotland was 61,840, said Sir Andrew Davidson, speaking at the Council of Social Service Conference at Perth on Feb. 14. Of these the surgical group (amputations, injuries, and diseases affecting the bones and joints) accounted for nearly 29,000, the medical group (rheumatic conditions, diseases of the heart, lungs, nervous and digestive systems, and the skin) nearly 19,000, the psychiatric group nearly 3,000, and the remainder (congenital malformations, deafness and other ear troubles, blindness and other eye diseases) over 11,000.

The preventive aspect was being tackled from social, nutritional, and industrial health angles. A striking example was the improving figures for pulmonary tuberculosis, largely attributable to the higher standard of milk production. In 1937 there were 769 herds producing certified and tuberculin tested milk, now there were no fewer than 3,729. Blind persons in Scotland numbered roughly 9,000. Blindness in the young was decreasing, mainly due to the advent of new drugs and to better maternal and infant welfare. Schools for the deaf provided for 661 children, but the waiting list numbered 122 and included children over 9 years of age who had never been to school. Inadequate school accommodation and the lack of trained teachers were the main factors against progress.

Since the war a good start had been made in Scotland towards a scheme for the treatment of orthopaedic cases. Orthopaedic centres had been developed at seven hospitals in the E.H.S. of the Department of Health, where over 2,000 beds had been provided. That number was now less owing to diminished requirements and the shortage of nursing staff. Each hospital had a specialist staff, each unit had been supplied with the necessary equipment for physiotherapy and handicraft workshops for occupational therapy had been provided. After-care clinics were being set up in connexion with the main

centres and in collaboration with voluntary organizations and local authorities. A further welcome development had been the association of the universities and medical teaching schools with regional orthopaedic schemes. Lectureships had been created in Glasgow and Dundee, and similar appointments were being made in Edinburgh and Aberdeen. Of educable mental defectives Sir Andrew said all larger authorities and some smaller ones had provided special schools or classes but there were still many areas, particularly rural, where facilities were few and no institutional provision had been made. Some such areas had contracts with existing certified institutions but at present these were often not available on account of lack of accommodation, and children had to remain at home and in some cases attend the local school. Many who were interested in these matters considered that more adequate ascertainment was needed by specially qualified medical officers.

Defects of temperament and behaviour had only comparatively recently been recognized as worthy of special study and treatment. Now that we know, he said, to what extent the temperament of a child and the trend of character development are determined in the first five years of life, it is easy to see how important it is for maladjustment in young children to be detected and given skilled treatment at as early a stage as possible to prevent juvenile delinquency and neurosis developing at a later date.

Sir Andrew concluded by saying that the Department of Health was making a survey of existing rehabilitation facilities to determine at which hospitals they might best be developed in the future. The Disabled Persons (Employment) Act, 1944 constituted the most comprehensive piece of legislation in the history of the welfare of the disabled. Success in resettlement depended largely on the attitude of employers, especially foremen, and on the person's own determination and keenness to succeed.

Preparations and Appliances

A THORACOPLASTY RETRACTOR

Dr R. LAMBERT HURT, surgical registrar, Chest Unit, Hill End Hospital, St Albans, writes:

The instrument shown below, the design of which was first suggested to me by Mr O. S. Tubbs, F.R.C.S., has been devised in order that an improved exposure may be obtained during resection of the anterior ends of the 2nd and 3rd ribs during upper thoracoplasty. At this stage of the operation the periosteal separation is of necessity done "in the dark" with

the consequent risk of damage to the pleura or internal mammary vessels. By the use of this retractor the pectoral muscles are readily held away from the ribs, allowing all the periosteal separation to be done under direct vision.

Although originally designed for use during a thoracoplasty the instrument is of use during abdominal operations—its long blade allows of deep retraction, the handle being well away from the operation field.

The instrument, in stainless steel, may be obtained from the Holborn Surgical Instrument Co., Ltd, London, E.C.1

Reports of Societies

AETIOLOGY OF CHRONIC RHEUMATISM

A discussion on the aetiology of chronic rheumatism took place at a combined meeting of the Medicine and Physical Medicine Sections of the Royal Society of Medicine on Jan 28. Dr MAURICE DAVIDSON presided.

Historical Introduction

Dr W S C COPEMAN said that the word "arthritis" was of great antiquity, it was used by Galen and his successors for infections of the joints of the body. As a generic term it included gout. Rheumatism and arthritis were explained in terms of the humoral theory until well on in the eighteenth century. Rheumatism was considered as the discharge of a catarrhal humour into the blood. Osteoarthritis was first described as a disease distinct from gout by William Heberden in his *Commentaries on Disease* published in 1802, the year after his death. The chemical view of rheumatism started about the middle of the nineteenth century and enjoyed a brief popularity. The name "rheumatoid arthritis" was coined by Sir Archibald Garrod. The term "rheumatic gout" was given to a disease in no way related to gout and not necessarily to rheumatism, and sometimes called "rheumatic arthritis". Charcot put forward his views in 1868, and the neurotrophic hypothesis associated with the name of Weir Mitchell lingered on until the end of the last century. Later came the view that rheumatoid arthritis might be primary or secondary. In 1909 A E Garrod suggested a metabolic factor, and this theory was taken further a few years later. The hypothesis of infection apparently first came into history in 1803, when an American physician, Benjamin Rush, cured a case of what appeared to be rheumatoid arthritis of the hip by the removal of an aching tooth. In modern times the theory of focal sepsis had been popularized by the late Sir William Willcox and others and had perhaps been too much exploited. Although osteoarthritis was a very ancient disease, it was not clinically differentiated from other forms of arthritis until 1829.

The Concern of the General Physician

Dr PHILIP ELLMAN, in a lengthy and comprehensive paper, declared the term "chronic rheumatism" to be ambiguous and unscientific. Before discussing the aetiology an attempt should be made, he said, to define and classify the conditions which were described as "chronic rheumatism". This description covered a group of diseases of the locomotor system, and constitutional disturbance might or might not be present. His own preference was for a return, with slight modifications, to the classification originally propounded by Sir Archibald Garrod in 1890. The classification suggested by a committee of the Royal College of Physicians in 1934, however, was probably the most comprehensive and scientific to date.

Chronic rheumatism was a disease of unknown aetiology, associated with morbidity rather than mortality, and treated in the main almost with indifference by the profession. The prevailing general attitude of defeatism in relation to rheumatic diseases as a whole and to chronic arthritis in particular was not justified. It was his firm conviction that rheumatic diseases were primarily the concern of the general physician working closely with the general practitioner rather than of the ultra-specialist. He had no wish to disparage the contribution which specialization had made and could make to this subject. Co-ordinated teamwork by the physician, the specialist in physical medicine, the orthopaedic surgeon, the physiotherapist, and others was essential, but the final assessment of the patient as a whole rested with the general physician who must interpret the local manifestations in relation to the general background.

Dr Ellman mentioned the effect of pregnancy. He had no record of arthritis developing during pregnancy, and cases had been described in which pregnancy had been a therapeutic measure. The potential significance of the pituitary in relation to chronic rheumatism had received considerable attention, and hopes had been raised with regard to irradiation of the pituitary. Among other aetiological aspects he touched upon the geographical distribution of rheumatism, a disease of temperate climates but he felt that faulty domestic heating and ventila-

tion was more potent than climate as a causative condition. He emphasized the need for taking a complete history of the patient. In how many cases was any real investigation made of habits and environment? He gave particulars of a survey of 100 cases of the rheumatoid type of arthritis, and mentioned incidentally, the large preponderance of women over men (in this survey 3/1), the age incidence (nearer 40 than 20), and other factors. He described some biographical studies which he and his colleagues had made on cases of fibrositis in civilian and Service patients during the war.

A Sensitization Factor

Dr G D KERSLEY discussed the phenomena of sensitization in relation to this problem. He first separated off cases of the osteoarthritic type. Generally speaking, these were characteristic in that they were joint affections only, and their aetiology was referable to two things—a predisposition in the joints which were generally of a poor type, and trauma most frequently repeated small strains, possibly arising from bad posture. With regard to the rest of the rheumatic group the more cases one saw the less sure one became. Each syndrome was completely clear in itself so far as the more typical cases were concerned but there were many intermediate cases and many common factors. Attacks might be started by a number of aetiological factors common to all the groups. In none of these syndromes had any specific infection been proved, yet in all of them it was not uncommon for any infection to bring on the condition or exacerbate it.

Was there any theory which could connect all these various factors? The only one he could suggest was an altered reaction to a foreign protein. Experimentally it had been shown that the local tissue reaction in sensitized animals was mesodermal only, and it did resemble in many ways the granulomata found in rheumatic fever and rheumatoid arthritis. It could be shown experimentally that that particular reaction might be confined to one area by producing a localized hyperaemia or by trauma or fatigue and these were exactly the factors which localized the phenomena in rheumatic conditions particularly in gout and in fibrositis. Another point in favour of the theory was the rheumatic pains and often the swelling of the joints which were not uncommonly found in the course of immunization for example, against scarlet fever. Again, when rheumatism in any form arose as a result of infection there was almost invariably a lag between the infection and the onset of the rheumatic stage, and the commonest time-lag was ten or fourteen days, which was also the common period for sensitization. Another argument for the theory of sensitization allergy was the reaction of many rheumatic conditions to salicylates and the complete absence of reaction of all rheumatic conditions to penicillin or the sulphonamides.

Accepting the possibility of sensitization as underlying the rheumatic state, the factors which might contribute to produce susceptibility to sensitization included hereditary predisposition, depression of antibody in the blood stream by reason of chronic infection, fatigue, exposure to climatic conditions, and upset of the autonomic nervous system occasioned by worry or shock, all these were common factors in the various rheumatic syndromes. He suggested as a possibility that an endogenous type of allergen was formed in certain cases in addition to the various exogenous allergens, and he thought that this opened up a certain field for research.

Perhaps because the openers had covered the subject so completely there was almost no general discussion, and the openers had nothing to which to reply.

VIRUS AND LABORATORY

Delivering the Chadwick Lecture, "Laboratory Investigations in the Diagnosis of Virus Infections of Man" on Feb 18 at the Royal Society of Tropical Medicine and Hygiene, Prof S P BEDSON said that although it was understandable that there should be some delay in the findings of research passing into everyday knowledge, in the case of virus work this delay was unduly long. Much of the work of the past fifteen years had gone unnoticed and insufficient use was made of the diagnostic procedures which virus research had made available. It was still widely believed that all viruses were too small to be seen with the microscope, yet in quite a number of virus diseases

microscopic demonstration of the causal agent was of diagnostic value. This was true of trachoma and of those conditions caused by the nearly related virus of inclusion conjunctivitis. The virus of lymphogranuloma venereum could at times be demonstrated in smears made from the inguinal buboes which occurred in many cases of infection with this virus and recent work had demonstrated the diagnostic value of the microscopic examination of smears made from the skin lesions of smallpox. Even where demonstration of the virus by the microscope could not be achieved, histological changes, such as inclusion bodies, could be looked for, their occurrence was always suggestive of a virus infection, and in certain instances, such as the Negri body in rabies, it was diagnostic.

Valuable though microscopy might be in the laboratory investigation of virus disease as in any infection the aim of the laboratory should be the isolation and identification of the causal agent. In the case of viruses this entailed the injection of experimental animals or eggs and establishing the viruses preparatory to their study. Unfortunately quite a number of viruses affecting man were so specifically adapted to man as to make it impossible to grow them apart from human tissues and even where animals or the egg were suitable the time consumed in identifying the virus made the procedure of little or no use for immediate diagnosis. None the less whenever the diagnosis was in doubt attempts to isolate and identify the causal virus should be made. It was still far from being generally appreciated that the serological reactions employed in bacteriology were equally applicable to the identification of viruses or the diagnosis of virus disease. Of these reactions the complement fixation test was probably the most valuable for virus work. It could be used either for the demonstration of the presence of the causal virus as was the case when it was applied to the diagnosis of smallpox, or it might be employed for the detection of antibody produced in response to infection, as in influenza, psittacosis, lymphocytic choriomeningitis, lymphogranuloma venereum, or mumps.

A REGIONAL MIDWIFERY SERVICE

At a meeting of the Manchester Medical Society on Feb 5 Prof DUGALD BAIRD said that the focal point of a regional maternity scheme should, if possible, be a university teaching hospital alongside the general hospital, the children's hospital, and the medical school. Placed conveniently in the district round the hospital there should be health centres which would be the headquarters of the family doctors and midwives engaged in domiciliary midwifery. An obstetrician on the staff of the maternity hospital should visit each centre each week to see women booked to come into hospital for confinement and to see in consultation with the family doctor any case about which he wanted an opinion. In the same way a member of the staff of the children's hospital would supervise and direct the child welfare work in conjunction with the family doctor. This would leave the out-patient department at the hospital free for the investigation of special cases.

The family doctors, midwives and health visitors based on the health centre would take part in the teaching of medical students and nurses. Such a scheme was well under way in Aberdeen except for the fact that the family practitioners worked from their own homes and not from health centres, and played less part in the scheme than they would if they were working from a well-equipped centre. Each doctor must be made to feel that he or she was an essential member of the team supplying a first-class service for the area. To promote this frequent clinical meetings should be held at the hospital, when problems of organization, results of treatment and recent advances in the subject could be discussed. There should be a good records department where the details of every confinement not only in hospital but in the whole area could be analysed. In this way problems could be investigated on a much wider basis and attacked from the laboratory, statistical and social aspects. Very many problems in medicine as well as in midwifery were urgently in need of study by some such organization. In this way too, the efficiency of the service in one area could be compared with that of another.

During the last ten years in Aberdeen maternal deaths, stillbirths, and neonatal deaths had been analysed for the whole

area by the obstetrical staff of the hospital in conjunction with the medical officer of health. Analysis of the figures had led to clear conclusions being reached as to the deficiencies in the present service. It had shown that the use of sulphonamides and penicillin had practically wiped out deaths from puerperal sepsis. The death rate from eclampsia had been halved in the last ten years. Under the Maternity Services Scotland, Act it was calculated for the purpose of assessing fees that the doctor would make three antenatal visits. This was quite inadequate. The death rate from shock and haemorrhage had diminished least so that there was still room for improvement in the management of abnormal labour.

Wife experience had shown conclusively that in the prevention of deaths of mothers and infants much attention had to be given to the health and diet of the mother. The problem of a good obstetric service was a very much wider one than that of keeping up the standard of medical and nursing skill. The measures taken to lower mortality would also help to lower morbidity. There was still a lot to be done to make a first-class service available to every mother at a reasonable cost.

CATERING FOR THE AGED AND INFIRM

A conference on "Special Forms of Catering for the Aged, Invalid, and Infirm" was held by the London Council of Social Service on Jan 18 under the chairmanship of LORD AMULREE. Representatives of many statutory and voluntary bodies attended.

Dr F. AVERY JONES pointed out that with the limited supply of home helps and domestic servants many people were unable to get proper meals while they were ill, so that recovery was retarded. Old people and convalescents, unable to cope with shopping and cooking were similarly affected. At least 10% of the admissions to hospitals were not for specific treatment but for rest food and medical supervision which given proper facilities, could be provided at home. A food delivery service providing cooked meals for such people should be established in every borough and feeding centres for those in need of special diets (a preliminary survey in London factories showed that over 5% of the men had, or had had a gastric or duodenal ulcer) he referred to the advisory service provided by the Invalid Kitchens of London to assist works canteens in catering for employees with special medical needs. Such facilities as these, and a campaign against obesity—an extra stone (6.3 kg) in weight at middle age lessened a man's expectation of life by 10%—could also do much to keep people out of hospitals.

Dr MAGNUS PYKE showed that while the calorific needs of the aged were rather less than for younger people their nutritive needs were as great. Research recently carried out in Vienna—where there had been severe food shortages—showed that loss of weight through malnutrition occurred more severely among old people. Surveys must be carried out to discover what kind of a diet old people were eating.

Mr FRED MESSER M.P., advocated the provision of more "home helps" to assist old people in preparing the right kind of meals and to help keep them out of institutions. A common dining room would help old people living in specially built groups of houses or flats. In other cases mobile services should take the meals in containers. In the past such services had been left to voluntary agencies and he did not want to dispense with the valuable personal service which they rendered but while they should retain their function the expense should be borne by the community and the responsibility for this and other aspects of old people's work should be assumed by the local authority. Good food and good cooking in hospitals were often spoilt between kitchen and patient, and each hospital should be provided with a catering manager to see that the right kind of food was provided in a palatable condition.

For the last session Miss ROSE SIMMONDS and Miss KATHLEEN PROUD opened a discussion on luncheon clubs and mobile meals services. It was not generally realized by catering officers in factories, convalescent homes and restaurants that special diets could often be prepared from the same food as that served to ordinary customers—the meat needed to be minced, the vegetables sieved and the steamed pudding served without fruit but with a sauce. Simple adjustments could also serve the obese, diabetics and old

people Mobile meals services should serve maternity cases, convalescents, and the chronic sick, especially the aged Vans equipped with thermostatic containers should operate from communal meals centres, leaving the meals at people's homes and collecting the containers left on the previous day The Invalid Kitchens of London was a voluntary organization serving mobile meals in six London boroughs, in only one receiving assistance from the local authority In eight other boroughs mobile services were provided by the local Council of Social Service, Old People's Welfare Committee, Red Cross or Women's Voluntary Services

In summing up LORD AMULREE emphasized that there was a great shortage of hospital beds and any special feeding arrangements that would help to keep people out of the hospitals would be a valuable service to the community He advocated the appointment of meals supervisors in hospitals and institutions The present arrangements for the care of old people were inadequate and local authorities must take their part in this work Old people should be allowed to take their own furniture when they went to a special home or institution

Mr GEORGE MITCHELL, Chairman of the London Council of Social Service, in thanking Lord Amulree and the speakers said that his Council had been responsible for a good deal of pioneering and research in connexion with communal feeding

"THE SHORT ANAESTHETIC"

At a meeting of the Devon and Exeter Medico Chirurgical Society on Feb 20, Dr W A WALTER discussed those anaesthetics commonly used in general practice

It should be borne in mind, said Dr Walter, that gas anaesthesia was achieved solely by producing a state of partial asphyxia For dental extractions it was intended to be short but occasionally became a protracted affair After such an experience the patient might be none the worse but in one long series reported in the United States there had been eleven cases of sudden death, one case of prolonged decerebrate rigidity ending fatally and a case of marked and apparently permanent mental deterioration in an unusually intelligent child The anaesthetist had to decide whether to call a halt or to risk damage to the patient's cortical cells

Domiciliary anaesthetics were required for minor operations but there was no such thing as a minor anaesthetic Intravenous thiopentone (pentothal) had much to commend it provided that certain precautions were observed There should be no premedication there must be an unobstructed airway, and the patient should not have taken food for three to four hours beforehand There was danger of asphyxia in the recovery stage, especially after premedication or after a large dose of thiopentone There was also a risk of laryngeal spasm with this drug When administering thiopentone in a patient's home, the anaesthetist should have with him at least twice the amount that he expected to use, tongue forceps, nikethamide and if possible a cylinder of oxygen He should not leave the house until the patient was able sleepily but sensibly to answer questions and he must instruct some relative or the nurse not to leave the patient unattended until he was fully "round" and talking rationally

For the senile, the anaemic and the septicaemic thiopentone was undoubtedly preferable to gas Senile patients required far less than younger subjects The dose given should be the smallest required to produce the desired effect and the rate of administration could be controlled conveniently by using a fine needle say a No 17 The patient usually became unconscious with a contented sigh This degree of anaesthesia should give two or three minutes of relaxation If a longer period was needed as much again of the drug should be given slowly keeping careful watch of abdominal respiration If the breathing stopped the administration should be stopped at once until breathing started again If it did not start again soon artificial respiration should be begun before the patient lost his pink colour Oxygen was better than fresh air, but the latter was to be preferred if there was any delay with the oxygen To produce local ring analgesia for a whitlow by repeated injections was a painful process While it was being done the patient should be given gas and air, by a self-administering machine or trilecne, through an inhaler

The Pemmican G M J

SIR—May I congratulate the *BMJ* on having, almost alone among periodicals (suspended by an 'illegal ukase'), defied successfully the latest effort to establish totalitarian methods by our egregious Minister of Fuel These two pemmican substitutes should find an honoured place in the archives of the *BMJ*

The position was clarified by two debates in Parliament—in the Commons on Feb 25 and 26, and the Lords on Feb 27 Two explanations of the suspension were presented conflicting with one another and with the facts In both Houses the pretence of any statutory sanction was immediately abandoned On Feb 25 in the Commons the Prime Minister, challenged at question time for the statutory authority upon which suspension had been made, declared twice over that it was 'done by agreement between the Periodical Proprietors' Association (PPA) and the Government Lord Chorley, replying for the Government in the Lords (Feb 27), repudiated the 'agreement' argument 'Suspension of publication was secured,' he said, 'by an instruction issued after consultation with bodies representing major interests in the newspaper and periodical Press Speaking with all the authority of a Professor of Law in the University of London, he declared categorically that instruction is the word which I think most accurately describes' the procedure adopted

The ascertained facts are that Mr Shinwell had issued the 'instruction' three days before any consultation with the PPA was attempted The instruction had, and was intended to have, all the appearance of an imperial rescript The PPA, taking that view of it, and confronted with an accomplished fact, had no alternative but to 'agree' Your information conveyed in the pemmican issue and in the current *Journal* that you were officially scolded, not for using electricity which you had not done, but for coming out at all, is another illustration of effrontery in high quarters

But there is yet a further consideration of major importance It was well known that during this momentous fortnight the Minister of Health was to be engaged in critical negotiations with the medical profession, upon which he had very reluctantly embarked and only when faced with the wholesale revolt by the profession against his Act It is obvious that it might have been extremely convenient for the Minister to prevent during these negotiations publication of the medical journals whose duty and whose function it is to keep the profession fully informed on matters of such vital importance to it The possibility of such back stage ministerial intrigues lends a sinister significance to this new encroachment on our liberties—I am etc

House of Commons

E GRAHAM-LITTLE

SIR—Reading the *BMJ* No 4494 prompts me to send congratulations to you and your staff on account of the way in which you manage to carry on in the teeth of appalling conditions! The spirit behind that copy certainly deserves our admiration Just at present we too, in Denmark, are shivering and talking about fuel but spring cannot be far behind—I am, etc

Randers Denmark

OLE BANG

SIR—Congratulations to yourselves and your 'printer' on this week's *Journal* It raises our confidence in the Association's perseverance in other spheres—I am, etc,

Ross Herefordshire

G M LLOYD

SIR—I write to express my appreciation and admiration for the last two issues of the *Journal* It is gratifying that even in these sad times there are still people who show initiative—I am, etc,

Liverpool

ISABELLA FORSHALL

SIR—Enormous congratulations on maintaining the freedom to print *Prosit omen! Floreat libertas!*—I am, etc,

London NW 3

L W

SIR—"Peace hath her victories no less renowned than war" could hardly be better illustrated than by the abbreviated *Journal* of the last fortnight, upon which, Sir, the profession must most warmly congratulate you

May I plead that some of this excellent editorial précis writing is continued? Without it how many of us would have learnt that "outfitters won't give long trousers to son aged 7 without doctor's certificate", "certificates must be renewed that leg still off each time applying for extra soap allowed", or the story of the night porters and the hansom cabs *Floreat brevior BMJ*!—I am, etc.,

London W 1

HENRY WILSON

SIR—I feel I must write and congratulate you on your two fine efforts. You and your staff deserve the highest praise for a grand show. If our rulers had half the guts you people have our country would not be in its present condition—I am, etc.,

Hemel Hempstead

E S PHILLIPS

SIR,—While not particularly anxious to dim the glow of complacency which I presume, appears on the faces of all at BMA House, I must protest against your efforts in producing the *BMJ* during the fuel crisis

In my opinion only two courses were open to you either (a) fall in line with good grace like the other periodicals, or (b) defy the 'ban' and produce the *Journal* as usual, since no legal proceedings could have been taken against you. Sixty-two thousand sheets of paper and sixty-two thousand envelopes—what a waste of paper and effort!

The first issue I scanned with startled amazement, the second I put at the back of the fire unread. Am I alone in my feelings in this matter?—I am, etc.,

Nelson Lancs

A J P DALY

Statistics Retrodisplacement and Fertility

SIR,—The burdens of the research worker in medicine have been added to in recent years by the vociferous advent of criticism from the statisticians. Conscious of the immense amount of labour that has gone into the preparation of even a short paper he is apt to resent what he considers are the facile criticisms of the man who wields a slide rule in an arm chair. It is indeed much to be regretted that so often the statistician's summing-up ends in the words "Your data are insufficient on which to base any conclusion". Of course such a picture of the statistician as a sort of kill-joy is extremely one-sided. On the contrary, statisticians have repeatedly pointed out that ignorance of statistical method may lead to a conclusion *not* being drawn, that significant answers to questions may be missed.

In the hope that this preliminary apology will avert wrath, I would like to discuss the article by Mr H H Fouracre Barns, "Retrodisplaced Gravid Uterus" (Feb 1, p 169). It is not my intention to deal with the logical errors in his conclusions, for they do not make much difference in the end, and in any case they are no worse than is to be found in many other articles. His general conclusion, that his figures do not disprove the hypothesis that retrodisplacement (without incarceration) does not significantly predispose towards abortion (I hope he will accept my re-wording) is quite correct. It would have been easier for his readers to see if he had arranged his figures (p 170, col 1) in a table

TABLE I—Incidence of Abortion up to Twelfth Week of Pregnancy

	Aborted	Not Aborted	Total
Retrodisplaced uterus	2	25	27
Not displaced	54	393	447
Total	56	418	474

It is scarcely necessary to do a χ^2 test to demonstrate that there is no significant difference in the number of abortions in the two types of uterine position

Hidden in the mass of figures in his article are some which are of profound significance. Mr Barns quotes the figures of Polak 1926, who found "18% of congenital retroversions in nulliparous women and 35% in post-partum women". Mr Barns found, at University College Hospital the following

figures 381 primigravidae of whom 21 had a retrodisplaced uterus, and 93 multiparae, of whom 6 had malposition. If we take a comparable number from Polak's figures (the conclusion is even stronger if we take his total number) we can arrange them as follows

TABLE II—Incidence of Retrodisplacement of the Uterus in Nulliparous Women

	Displaced	Not Displaced	Total
UCH pregnant	21	360	381
Polak not pregnant	69	312	381
Total	90	672	762

$$\chi^2 = \frac{(69 \times 360 - 21 \times 312)^2 \times 762}{90 \times 672 \times 381 \times 381} = 29.1 \quad P = \text{less than } 0.001$$

The test means that if there were no difference in the incidence of pregnancy between the women with displaced uterus and with normal uterus, the chances of getting such figures are less than one in a thousand. The discrepancy is due to the small number of pregnant women with displaced uterus. The figures clearly disprove the hypothesis that displacement has no deleterious effect on the incidence of pregnancy, and they disprove it as conclusively as could be desired. I would hasten to add that this does not invalidate Mr Barns's statement "that any woman complaining of sterility in whom the only abnormality to be found is a retrodisplaced uterus should be investigated and treated along the same lines as would be a woman with an anteverted uterus". Retrodisplacement is only one factor in the causation of infertility, and careful investigation is the common-sense procedure of the careful surgeon who does not rush to operate without sufficient reason.

A measure of the association between retrodisplacement and infertility may be obtained from the above figures. Since the variables fall each into two definite categories, the best coefficient would be the ϕ coefficient, which is the correlation for point distributions. This comes to just below 0.2 which explains why although the association has been observed, there has been much uncertainty over it.

A similar table could be constructed comparing the UCH multiparae with Polak's post partum women, but on turning to the original statement of Polak I find that he declares that post partum retroversion is not a fixed condition but may return to normal in the course of several months. The two sets of figures (UCH and Polak) are therefore not comparable, and conclusions drawn from them may be fallacious. This point reinforces the oft repeated statements of my teachers: statistical techniques are only the numerical form of the logic of scientific method: the right time to consider statistics is before an investigation is begun, not when it is over.—I am, etc.,

London WC 1

M HAMILTON

Intestinal Myiasis

SIR,—Dr Alan M Easton has been kind enough to send me an article with the above headline published in this *Journal* by Dr D S Sharpe on Jan 11 (p 54). As my name is mentioned in that report it may easily be inferred that I concur with the views expressed in it. I am therefore compelled shortly to discuss the matter in this *Journal*. When returning the larvae and stating their scientific name as *Pinus tectus*, Boield, I added "It is hardly possible that the specimens should have passed the stomach of the patient, and I suggest that they have got into a vessel used for receiving or transmitting the excrements." Unfortunately the author did not mention this warning in his report and it appears therefore desirable to elaborate my statement in the following lines

The evidence for an actual passing of the larvae in the stool of the patient does not hold good to scientific scrutiny. The account does not mention in what type of vessel the stool was examined by the patient nor where this vessel was kept before use. It has obviously not been a water-filled lavatory basin, and there is a great possibility of the larvae having fallen into the vessel from some infested material, such as a mattress, cushion, blanket, or the like. As the larvae are of a more or less creamy colour they would be all intents and purposes be invisible to a layman if lying in the usual type of vessel.

On the other hand there are very serious reasons for disbelieving any possibility of these creatures having passed the intestine. The chemical objections have to some extent been considered by Dr Sharpe, and he himself discounts the possibility of the soft-kinned larva resisting the protein-digesting secretions of the stomach. He therefore assumes that the eggs with their "resistant chitinous coating" can pass the stomach unharmed and that the larva can hatch from the egg in the more alkaline portion of the bowel. In actual fact the egg membrane of the *ptinids* is very fine and thin, and in the absence of experiments does not justify the assumption of its being much more impervious to pepsin and hydrochloric acid than the chitinous integument of the larva. In order to obtain conclusive evidence on this subject I have treated eggs, newly hatched larvae, and almost full grown larvae of *Plinus tectus*, which were kindly placed at my disposal by the Director and Mr R Howe of the Pest Infestation Laboratory, Department of Scientific and Industrial Research, with artificial gastric juice. The specimens were first admixed to chewed bread and the experiment was kept at 36-38° C for three hours. The material was then washed in distilled water and scrutinized under a dissecting microscope. Full grown and newly hatched larvae were dead but not disintegrated, and larvae more or less ready for hatching had been killed inside the eggs. There is no evidence so far (after ten days) that any of the less developed eggs have hatched. The fact that young larvae have definitely been killed inside the intact egg-shell seems to prove at any rate that the egg shell does not afford a considerable protection against the influences prevailing in the human intestine.

Dr Sharpe has also stressed the mechanical difficulties for the larvae of remaining in the intestine for a period of a week or more in view of the action of the peristalsis. According to him the larva holds itself in position by its claws and jaws. In actual fact the rather thin claws would probably be of little avail, while the jaws would be wanted for the ingestion of the food so that they could not possibly keep their grip. On the other hand this point is of minor consequence, as an insect larva of this type developing in the intestine would find a nook at the base of the villi or somewhere else where it would be relatively safe, and it would soon create a small excavation round its body in which it could rest securely.

Plinus tectus lives in dried animal or vegetable matter, such as dried crayfish (e.g. of collections or of food for aquarium fish) and casein (in which latter it is a regular pest) on the one hand, and in rye, maize, cayenne pepper, cocoa, ship's biscuit on the other hand. It is therefore very well adapted to a life in a medium containing between 5 and 15% humidity. The larvae would however, be quite unsuited to a habitat in a stiff semi-liquid material with a moisture content of more than 90%, as is found in the human intestine, and they would very quickly be clogged up and asphyxiated. While experimenting with artificial gastric juice I kept another batch of eggs and newly hatched and almost full-grown larvae in chewed bread in a moderate quantity of saliva without gastric juice for 31 hours at about 20° C. This treatment, too, killed the larvae but it is too early yet to decide whether all the eggs have been killed in this experiment. Mr Howe has informed me of some tests with much lower degrees of humidity in hygroscopic foods with an estimated water content of up to 40%. As only a small percentage survived in these materials it is obvious that a further increase of the water content would soon prove lethal, as shown in my own experiment.

The gravest reason, however, for scepticism is afforded by the question of temperature. It is known from experiments with eggs of the flour moth (*Ephestia kuehniella* Zell.) an insect which lives under very similar ecological conditions, that they cannot hatch but will perish at a prolonged exposure to a temperature of 34.4° C or more. Even in a moist cell it has not been possible to raise this temperature (Häse, A., 1927 *Arb. biol. Reichsanst. Land u. Forstwirtschaft* 15: 116). As to *Plinus tectus* itself Mr R Howe informs me from his experience gained at the Pest Infestation Laboratory, that only large larvae survive for long at 28° C or above, and that only few first stage larvae reach the second stage at all at moderate temperature as 29° C. The most conclusive point against Dr Sharpe's view, however, is the fact that according to Mr Howe's experiments eggs do not hatch above 28° C so they would hardly remain alive for a day and certainly never hatch at the temperatures prevailing in the human intestine.

Lastly a point of terminology should not pass without comment. The term myiasis derived from *μυζ*, a fly, designates the infestation of any part of the body of living animals by the larvae of diptera or two winged flies (Smart J 1943, *A Handbook for the Identification of Insects of Medical Importance* p 810 London British Museum). A similar infestation by beetles or their larvae is called canthariasis. Entomologists have for some time been aware of the fact that many reports of myiasis and similar ailments collapse on closer examination and modern textbooks like that of Smart duly stress the necessity

for a thoroughly critical examination of each reported case. My personal impression is that in temperate European countries the larva of the lesser house-fly is most likely to produce genuine cases of myiasis, and that certain tyroglyphid mites can probably produce similar and sometimes rather serious symptoms.

I would like to express my thanks to the Director and Mr R Howe, Pest Infestation Laboratory, Department of Scientific and Industrial Research, Slough, Bucks., for breeding material of *Plinus tectus* and for the information cited above, to Mr N D Riley, Keeper of the Department of Entomology, British Museum (Natural History), and Mr F Barnett of the same Department for their, unfortunately unsuccessful, efforts at obtaining a quantity of pepsin for me and, lastly, to the John Innes Horticultural Institution for providing me with this substance.

—I am, etc.,

Imperial Institute of Entomology

F I VAN EMDEN

SIR,—I was most interested to read Dr D S Sharpe's account of a case of intestinal myiasis caused by the larva of *Plinus tectus* (Jan 11 p 54). I am, however, startled by his implication that the larva of *Plinus tectus* is insectivorous and I should be glad to know which insects normally form the food for this larva.

I feel also that Dr Sharpe may be adding to the anxieties of parents by his lurid threat of intestinal myiasis to those children who eat fallen fruits. The only dipterous families which are likely to infest fruits attractive to even the most omnivorous (or insectivorous?) child are the Trypetidae or the Drosophilidae, and so far as I am aware no member of these families has so far been incriminated with causing myiasis. The adults of the Muscidae and the Calliphoridae—the myiasis-causing species *par excellence*—certainly feed on fermenting fruit, but I think they prefer a rather more decayed pabulum for breeding purposes.—I am, etc.,

Control of Measles

SIR—After a depressing week-end of Arctic weather snow shifting, and fuel crises (national and domestic) it was a welcome relief to open the *British Medical Journal* and read the three leading articles (Feb 8, p 225). The first of these ably reviewed the present position with regard to the control of measles, a very topical subject, the second set out clearly the reasons why a severe outbreak of influenza is unlikely this winter, while the third had the significant title "The Minister Accepts".

I found myself in general agreement with the opinions expressed in the article on the control of measles but would like to make one or two comments with regard to the availability and use of convalescent measles serum, normal adult serum, and gamma-globulin. The last is at present unobtainable, while convalescent measles serum is in my experience a very rare product indeed, but adult normal serum could and should be readily available for the use of any doctor requiring it.

From the beginning of this year Leeds doctors have been able to obtain adult measles serum through the Public Health Department. The supply is obtained by arrangement with the Regional Blood Transfusion Service, who kindly carry out the necessary bottling and undertake the essential tests. The few weeks that have elapsed since the inauguration of this scheme have already proved its value, and in addition to numerous inquiries from doctors within the city there have been several requests for serum from areas outside the city and two from as far afield as Newcastle so that it would appear that as far as the north-east of England is concerned the facilities for obtaining this product either do not exist or are not sufficiently well known. In this latter respect the statement in the leading article that normal adult serum is available from most of the constituent laboratories of the Public Health Laboratory Service was news to me and I am sure it would be helpful if further publicity could be given to this source of supply.

I have found that some confusion exists as to the use of adult serum for attenuation. In one or two instances the serum has been given to the case rather than to the contact. Claims have been made as to the value of convalescent and adult serum in the treatment of a case of measles but these have not been substantiated. When using adult serum for prevention the usual dose recommended is 10 ml, and this should be given

contact not later than the day of the appearance of the rash in the infecting case. If used for attenuation the same dose of 10 ml should be given to the contact on the 4th, 5th, or 6th day after the appearance of the rash in the infecting case—I am, etc.,

Leeds

J F WARIN

National Health Service Act

SIR—It is with diffidence that I enter the controversy on the National Health Service Act. It would appear that everything has already been said many times over on either side. However, it seems to me that the minority who voted "Yes"—a minority that was nearly 50%—should be more often represented in your columns. I particularly disagree with the claim made by so many of your contributors that opposition to the Act is not based on politics, or, at any rate, on party politics. Personally I am not a Socialist and have never voted for any party, and, considering the complete political unreality of so much of the argument, it is obvious that most medical men are not actively engaged in political life. Nevertheless, how many are there of those opposing the Act who do not cast their vote for a Conservative at an election? Professionally and socially we are predominantly Conservative and are naturally suspicious of a Labour Government and antagonistic towards its efforts. The people of this country, however, elected that Government with an overwhelming majority in Parliament. It is idle to pretend there was not a widespread determination to obtain social security, and votes were given to a party that could be trusted sincerely to support it. That was the working of democracy. Is it democratic for a section of the community to oppose the wishes of the majority as expressed in an Act of Parliament? Is it not dangerous to suggest that an organized professional body should try to make an Act unworkable in order to change it? Are we going to support miners or transport workers who might try to do likewise?

The Act sets out to effect a revolution—that no longer will poverty and lack of means be a bar to obtaining the best medical facilities and treatment available. Revolutions always disturb established customs. Such a great social advance cannot be made without some risks and disadvantages. Let us remember the advantages it will gain for our patients and potential patients, and be particularly careful that we are sincere when we claim to oppose the Act on behalf of our patients. When we complain because in time of scarcity extra amounts of rationed tit-bits are refused to a dying man who can afford them, it is well also to remember those who have been condemned to death or persistent ill-health through inability to afford necessary medical treatment.

It is for the individual doctor eventually to decide whether to enter the Service or not, but the recent plebiscite has finally destroyed the claim for unity within the profession. A large proportion of doctors, especially the younger ones, are willing to build up the best possible medical service on the present Act. Alterations in medical practice are part of wider social and economic changes hastened on by the war and are inevitable. The inherent danger of bureaucracy can be defeated by the efforts of those determined to make the Service successful. It is therefore to be hoped that in the coming negotiations the profession's representatives will display the utmost statesmanship and realism. Could the Minister be blamed for having failed to discuss previously the Act with a body so out of step with the times that it opposed a medical service covering 100% of the population? The Act is now on the Statute Book and we have our last chance to offer expert advice in clothing its bare bones—I am, etc.

Tunbridge Wells Kent

D G ff EDWARD

Freedom of Choice

SIR—We are most of us concerned with the imminent prospect of State control and of course hold freedom of choice of doctor by patient to be essential. Just how much freedom of choice the patient will have may be surmised from the following recent example. Mr A is a non-industrial Civil Servant. He is an insured person and is under treatment by me for severe thrombo phlebitis of leg. A few days ago he received from his department—namely the Assistance Board—a letter stating

that his case had been referred by them to the Treasury medical adviser—the object of this being to enable remedial action to be taken.

The Treasury medical adviser directs the Assistance Board to obtain an independent medical report from Dr B who is a general practitioner in the same area as myself. Since Mr A did not chance to select Dr B for his own doctor however, he is treated with scant courtesy by Dr B who when informed of the complaint refuses to visit him and insists upon his turning out and walking to the surgery with a thrombosed leg on dangerously ice-bound and snow covered roads. Mr A is then informed that he will probably have to attend again for a further report. All this happens without any notification to me as Mr A's doctor or any report on his condition being requested.

To comment on this it may be summarized by saying that Mr A, while under treatment by a doctor he wishes to attend him, is suddenly directed by the State as his employer to visit Dr B, whom he does not wish to attend, so that the Treasury medical adviser, who has never seen him may decide what treatment should be given. All this takes place in a most underhand way completely behind the back of his own doctor who is neither consulted nor informed of what is going on. Now Mr A cannot be simultaneously treated by two persons so pursuing this to its logical conclusion either the State removes him from his own doctor or if he elects to continue treatment from his own doctor it may threaten him with withdrawal of his salary. The most disturbing feature is that this is apparently standard procedure, the letter to Mr A being a cyclostyled copy bearing the form number G46/200/779—I am, etc.,

Greenfield Lancs

R S HOLGATE

Administrators of the Act

SIR—There is one seldom mentioned side of the National Health Service which I hope our negotiators will not overlook: the method of appointing the whole-time medical administrators. Whatever the final form of the Service it is clear that considerable executive authority will be vested in the statutory councils, boards, and committees envisaged in the Act. They however, will consist for the most part of part-time members and therefore considerable discretion and authority must devolve on their senior permanent officials, who will include medical men. It is our concern to see that from the start the method of appointing these key officials avoids the worst features of bureaucracy.

In my view at least two conditions must be fulfilled: (1) All senior appointments must be advertised and so thrown open to the widest possible "field". (2) Selection to medical appointments must be made by bodies on which there are representative medical members. This could be done peripherally by the body for whom the candidate is going to work or centrally by the Central Health Services Council. Any system which makes these appointments plums with which to reward long and faithful service in the existing medical administrative departments will I am certain prejudice fatally the prospect of getting a smoothly running service. Moreover I fear that unless we take steps to ensure the contrary this is the method of appointment that is likely to be applied—I am, etc.

Plymouth

T A A HUNTER

Remuneration under the Act

SIR—Now that discussions have begun between the Negotiating Committee and the Minister may I draw attention to a fundamental point hitherto overlooked? It is the method of remuneration by capitation fee—surely one of the worst evils of the N.H.I. scheme and now alas, threatening to be an even bigger evil in the future comprehensive Health Service. I think I am right in saying that the majority of doctors like other members of the community, prefer to be remunerated in accordance with the amount of work they do. Conversely they do not wish to be paid for anything they have not done. Nor is this feeling confined to the doctors, it is shared by patients: many of whom feel when they need attention that they have to apologize to their panel doctor for bothering him. How different many patients would feel if they knew their doctors were being paid on a *pro rata* basis for their time and trouble. As an example with the best intentions in the world human

weaknesses being what they are, there can be little doubt that a night call several miles into the country is done less grudgingly and more efficiently if there is a commensurate reward. It is the all-important incentive that counts.

For the future Health Service I strongly advocate a system of *pro rata* remuneration by the State on the lines of the familiar Form 1667 payment of civilian medical practitioners by the Service departments. The additional clerical work involved would in my opinion be more than worth it and no doubt the Minister could devise some method of ensuring that all claims were *bona fide*—I am, etc.,

Launceston Cornwall

R J HEALEY

Negotiating Committee and Consultants

SIR—When a specialist who has been on the staff of a hospital reaches the age limit for that particular hospital—usually 65 years, sometimes less—he is generally ‘promoted’ to being a consultant, and while he ceases to carry out any routine work at the hospital he by no means always ceases to carry on his private consulting work. So far as it is possible to judge the State Medical Service will deprive such consultants of most if not all, of these patients.

There appears to be no provision in the Act for any compensation to these men for the loss of their practices—often increased, owing to having more time to give to them, and carried on for a number of years after their retirement from the hospital staff. There must be a very large number of such specialists in many branches of the profession in practice to day, and I suggest the Negotiating Committee should insist that one of the numerous Regulations which undoubtedly will be made shall ensure a pension or compensation of some sort for these men, unless of course the State is willing to take them into its service—unlikely on account of age—I am, etc.

Norwich

ARTHUR GREENE

Medical Certification

SIR—The incursions of the bureaucrat into our professional freedom increase apace, and I am gratified that you have found space in the *Journal* of Feb 15 (p 268) to give vent to the protestations of Dr Basil S Kent against the personal data required by the Board of Trade before it issues a permit for the acquisition of a ‘thermos’ flask. While I agree wholeheartedly with the stand taken by Dr Kent I regret that he did concede the diagnosis in the case of his particular patient.

A few months ago I had a similar, if more protracted, correspondence with the Board of Trade which, for the sake of brevity I summarize.

May 4, 1946. Myself to Board of Trade. Point out that a medical diagnosis is a matter of strict confidence between patient and doctor and request text or content of any Regulation requiring a doctor, after he has certified that in his opinion a patient requires a ‘thermos’ flask, to submit his diagnosis for the approval of a lay official before such flask can be obtained. May 6, 1946. Reply from B of T. Agreed that medical diagnosis is a matter of confidence but require certification that flask required for health reasons. May 7, 1946. Myself to B of T. Point out that no doctor is going to act merely in the capacity of a rubber stamp automatically endorsing applications for flasks, say for picnic purposes, and that a medical certificate is for nothing but health reasons. May 10, 1946. Reply from B of T. Permit for flask granted to patient, as it is gathered from my last letter that it is required for health reasons. Would be appreciated if, on future certificates this additional information could be given. May 17, 1946. Myself to B of T after a certificate to another patient had been turned down because of omission of the vital words ‘for health reasons’. Reiterate that medical certificates are only issued for reasons of *ill health* and not for flippant reasons. Suggest that a little less red tape would save paper postage, and manpower hours for the B of T as well as spare a busy practitioner a lengthy correspondence. Stated that I expected my original certificate to be honoured. May 21 1946. Reply from B of T. Permit granted. Stated that it would save the man hours which I mentioned if on future certificates I included the necessary words ‘for health reasons’.

What can one do Sir in the face of such obduracy? Incidentally I believe that ‘thermos’ flasks were on sale indiscriminately at a local ironmongers at the same time—I am etc.

Huddersfield

LESLIE BALLOX

The Spens Committee

SIR,—It is to be hoped when the Spens Committee issues its report that it will be couched in terms which can be understood by any trade unionist. The more obvious details such as wages, hours of work, and holidays are not likely to be overlooked, but there are more recondite matters which will require the exercise of the most precise judgment and discretion if discontent within the profession, leading to ‘ca’ canny’ ‘working to rule’ and strikes is to be avoided. The possibility of claims for ‘bending money’ from the obstetricians, ‘stretching money’ from the orthopaedists, ‘danger-money’ from the syphilologists, ‘dirty money’ and ‘wet-money’ from other departments which I shall not specify are only a few of the examples which could be given.

Remuneration on a sessional basis presents peculiar difficulties of its own. Is the pace to be that of the slowest? If so, production per man hour will suffer. ‘Time-studies’ would have to be introduced to avoid unfairness and consequent bad feeling. The good sense and dignity of the profession would be adequate to prevent cries of ‘No stop-watches here!’

Then there are degrees of skill and length of experience which will require their own assessment and reward. Surgical operations will have to be priced individually otherwise the craftsmen who do lengthy operations will be able to take more home in their pay packet each week than, say the ophthalmic surgeons. A careful delimitation of the various regions of the body will have to be carried out in order to avoid the unseemly disputes with regard to spheres of influence which are already arising. Rewards in kind, such as extra food and nylon stockings may have to be provided in order to maintain the supply of men in the more tedious and unpleasant specialties such as post mortem work.

The cost of production of a doctor is a point which may have escaped the notice of the committee, and I only touch upon it briefly in order to point out that it has been calculated by Socialist writers that the expense of training a doctor would be amortized over his working life by an increase of 5% above the wage of an unskilled labourer. This of course leaves out the question of ability, but it should be remembered that in a Socialist State there would be little ‘rent of ability’ allowed, the principle being ‘From each according to his ability, to each according to his needs’—I am, etc.,

Bournemouth

T R AINSLEY

Behcet's Syndrome and Vitamin K

SIR,—Dr E W Prosser Thomas's very interesting article (Jan 4, p 14) on this very serious and intractable complaint and Dr G Whitwell's letter (Feb 1, p 197), in which he states, ‘In view of the utter uselessness of all treatment up till now, any therapeutic measure would be welcome. The peculiar sensitivity of the skin would suggest a trial of ‘benadryl’’. I have prompted me to send a brief account of a very severe skin condition occurring in a friend of mine who had been treated over a period of 3½ years by a competent G P and three consulting dermatologists without any amelioration of his symptoms.

It was a case of seborrhoeic dermatitis of scalp, forehead, face, neck, limbs, and hands in which pin-point pustules as described by Dr Prosser Thomas developed like emboli the inflammation of one closing the left eye. There were in addition indigestion and intense sensitivity of the skin to light, heat and cold, and also to drugs such as sulphur and salicylic acid. Beyond some deterioration of sight there was no sign of gross eye lesions nor ulcer of the scrotum or aphthae of the mouth, so I do not know whether this was a case of Behcet's syndrome or not but in view of Dr Whitwell's remarks quoted above I should like to draw attention to the fact that after the failure of penicillin, injections of colloidal manganese desensitization by mag sulph colloidal sulphur vitamins A B C D nicotinic acid, thyroid, and ephedrine there was a dramatic cessation and disappearance of the pin-point pustules and consequent easing of the intolerable itching when I gave him a course of ‘acetomenaphthone’ (vitamin K analogue) 10 mg once a day by mouth. But this drug had no appreciable effect on the dry scaly seborrhoea, which, however yielded to shampoos and weak concentrations of ung hyd nit dil and olei cadmi.

In the *Practitioner* 1946, 157, 391 Dr D M Evans commented in a very valuable article on the benefits he has observed in skin and other diseases from the use of vitamin K analogue, and recently in "Any Questions" in the *Journal* (Jan 11, p 77) your expert stated that vitamin K seemed 'to exercise a beneficial effect in some cases of pernirosis—and this was borne out in the case I am recording where the patient said his cold feet were warmer after taking the drug. May I therefore suggest that vitamin K analogue should be given a trial in Behcet's syndrome and the result of such treatment recorded—I am, etc,

Paignton

A J AMBROSE

Vitamin H

SIR—In a recent paper some preliminary observations were reported about the relationship of premature alopecia and biotin by Chavarria *et al*¹. In Costa Rica a nutritional deficiency syndrome was studied by them during the last three years which appeared only in children and never in adults. Similar changes were described in Africa under the name of kwashiorkor² or infantile pellagra,^{3,4} but they were apparently considered manifestations of other deficiencies. The hair changes in Costa Rican children consisted of dryness, fragility, and loss of colour, the hair became loose and easily and painlessly pulled out, leading to calvities. Concurrently depigmentation of the hair varying from slight greying to intense whiteness occurred. The children often presented other deficiency symptoms such as follicular keratosis, seborrhoeic-like dermatitis, occasionally diarrhoea, generalized oedema with normal content of blood proteins and hepatic cirrhosis, glossitis, and angular stomatitis. The diet of the affected children consisted chiefly of bananas and molasses.

Unless the patient died shortly after admission the ordinary hospital diet effected a cure. An addition of 0.25 mg of biotin to the diet twice or three times a day appeared to accelerate the return of both pigment and growth of hair more quickly than the addition of thiamine, nicotinamide, and other vitamins—I am, etc,

Pellagrous Encephalopathy

SIR—I was interested in Dr P R Graves's account (Feb 15, p 253) of pellagrous encephalopathy occurring among prisoners of war in Singapore. In our camp at Palembang Sumatra, we had a similar syndrome, but had many more acute coma cases. These occurred mainly in the last three months of captivity, when the basic rice ration was 200 grammes per diem with very little vegetable and practically no protein foodstuffs. Most of the acute cases had previously shown well marked signs of pellagra and were all greatly emaciated. Some went from the ambulant stage into coma in the space of hours and on occasion a man failed to report at the morning roll call as he had in fact gone into a coma overnight in his billet. All showed quadriplegic rigidity but I cannot remember any case which had convulsions. We were able to perform only one or two necropsies and these very much *sub rosa*. It was possible to examine the brain *in situ* only. The hemispheres showed generalized oedema but apart from that little else was noted, and it was not practicable to open the abdomen—I am, etc,

J P CORCORAN

Intravenous Procaine (Novocain)

SIR—More is known about the effects of intravenous procaine (novocain) than is suggested in the reply to a question in the *Journal* of Feb 15 (p 282). Procaine has indeed quinidine-like actions on the heart which can prevent the development of auricular or ventricular fibrillation in experimental animals. Since however this action can only be produced on intravenous injection and probably only by doses that cause central nervous side effects, it is not likely to be of much therapeutic value.

Procaine has also been given by intravenous infusion for the relief of pain due to burns (Gordon R A *Canad med Ass J* 1943 49, 478), for the relief of the pain of labour (Allen, F M *Amer J Surg*, 1945 70 283) and for sundry other types of pain and in the relief of pruritus (Lundy, J S *Clinical Anaesthesia*, Philadelphia 1942). It has been suggested that this analgesic effect is due partly to a local action on a traumatized area where increased capillary permeability would allow greater amounts than normal to escape from the blood, and partly to an action on the central nervous system. For this purpose procaine has been given intravenously in doses of up to 5 g in 1½ hours.

It is important to realize that the toxicity of intravenous procaine is very closely related to the speed of injection since the compound is rapidly detoxicated, partly by an enzyme in the blood (called "procaine esterase" by Kisch, Koster, and Strauss) and partly by a similar enzyme in the liver. The procaine is hydrolysed to para-aminobenzoic acid and diethyl amino-ethanol, neither of which has the typical peripheral or central actions of procaine. If the rate of infusion exceeds the rate of breakdown the blood level of procaine will rise steadily, and toxic effects such as convulsions and respiratory failure will finally occur. Tachycardia usually appears when procaine is injected at rates exceeding 2 ml per minute of a 1% solution (20 mg per minute) and becomes marked when rates of over 5 ml per minute (50 mg per minute) are given. It is claimed that the convulsive action of procaine is prevented by pre-medication with barbiturates—e.g., pentobarbitone (1 gr (65 mg) by mouth).

The safety and value of intravenous procaine as an analgesic have not yet been adequately assessed. Studies on this subject are in progress in my laboratory at the present time—I am, etc.

Department of Pharmacology
Middlesex Hospital Medical School London W 1

C A KEELF

SIR—With regard to the question (Feb 15 p 282) on intravenous novocain (procaine) dosage it may be of interest to mention some unpublished facts on this subject. The writer has now administered procaine by vein in 48 cases mainly for post-operative pain in place of morphine. The routine dosage has been 1 g in 0.2% solution given over a period of 60–70 minutes. No deleterious effects have been noted and in general satisfactory analgesia has been obtained without the dangers of post-operative respiratory depression. This analgesia persists for as long as four days in some cases and its action is by no means clearly understood. Further investigations are at present being undertaken to determine effective blood levels consistent with safety and the mechanism of action of generalized procaine effects.

In addition to its analgesic effect intravenous procaine has a mild cerebral excitatory action which is beneficial in many post-operative cases. This effect may be very easily controlled by barbiturates, which have the further advantage of increasing the minimum lethal dose of procaine fourfold (Goodman and Gilman)—I am, etc,

London W 12

E J DELORME

Endocrine Receptors

SIR—We have to be grateful to Dr S L Simpson (Feb 15 p 270) for standing up in defence of endocrinologists who paid attention to the 'endocrine receptors' discussed by Mr Aleck Bourne (Jan 18 p 79) in view of your statement in the editorial review in the same number (p 96).

Due tribute should be paid however on this occasion to Prof Julius Bauer of Los Angeles California, formerly of the University of Vienna, who based his teaching of endocrinology on this assumption as long ago as 1917¹. The piquancy of the situation is the fact that in the summary of his works *Constitution and Disease* (Wm Heinemann London, 1942) he devoted a whole chapter to the discussion of this question (p 53). The book was extensively reviewed in your leading article of April 24 1943 (p 510) from which I quote 'Like H H Dale, he [Bauer] emphasizes the importance of the receptivity of the organ to hormonal stimulus, which explains cases where the endocrine lack is expressed in only one organ.' In a previous paper² Bauer explains the manifold activities of the pituitary hormones in this way.

Rediscovery of thoughts, teachings, and facts is by necessity more frequent as medicine and biology become more complex. It is to be hoped that the *World Abstracts* will be effective to cut down such occurrences to a minimum—I am, etc.,

Gynaecomastia

SIR—I was very interested to see that Dr Stephen D Sturton (Feb 15 p 269) calls attention to the enlargement of the breasts so often seen in male lepers. The condition was described in a book on tropical fevers by Dr Kauntze C M G and myself published in 1931 by Balliere, Tindall and Cox, and a photograph of a leper in Kenya Colony with this condition can be seen in the text—I am, etc.

Pinner Middx

N P JEWELL

Trilene in Labour

SIR,—Mr D M Stern (Feb 1, p 199) has stressed the dangers of using trilene for caesarean section. Many hospitals and clinics are unfortunately still not equipped with machines available for use with cyclopropane partly because there are not sufficient fully trained anaesthetists to administer it and partly because old established methods die hard, by which I mean the gas oxygen ether sequence. As there is often a cardiac or pulmonary indication for the use of cyclopropane in this operation I consider that authorities should make it their duty to install such an apparatus and a suitable anaesthetist to administer it.

Preliminary narcosis with morphine and hyoscine is admittedly inadvisable and therefore where cyclopropane is unavailable I suggest that the following technique should be adopted. Atropine is the only premedicant. A "sleep" dose of pentothal is administered with the patient on the table and the needle left in the vein. Gas oxygen and trilene is then induced, and only minimal doses of pentothal administered intermittently until the baby is born. Tachypnoea and cyanosis are avoided and more pentothal can be given after the baby is born to reduce respiratory excursion and allow the operation to proceed unhurried and unhindered.

Should tachypnoea prove troublesome or the dose of pentothal seem excessive resort can be gently made to vinesthene or even ether. Cyclopropane is undoubtedly the method of choice, but in its absence the above technique in my experience has proved safe and reliable in a large series of successful caesarean sections. The secret of success would appear to be the judicious and controlled use of a combination of pentothal with gas oxygen and trilene—I am, etc.,

Bristol

W M MAIDLOW

SIR—Having seen Mr D M Stern's letter (Feb 1, p 199) dealing with trilene anaesthesia for caesarean section, I have tabulated some of Dr F F Waddy's anaesthetics the notes of which cover all such cases performed at the General Hospital, Northampton which were anaesthetized by him and operated upon by Mr R Watson between Nov 30 1942 and Dec 16, 1943—about thirteen months. From these figures it is not possible to agree with Mr Stern's assertion that trilene with nitrous-oxide anaesthesia is harmful—let alone dangerous—to either the mother or to the infant in this type of case.

Maternal age range 19 to 47 average maternal age 32, maternal mortality 0 infant mortality 3 (5.3%) one stillbirth one asphyxia one unknown. In this series 57 caesarean sections were performed. There was one twin pregnancy and one stillbirth in which the foetal heart could not be heard prior to the operation. The state of infant at birth was good in 26 (44.8%) satisfactory in 10 (17.2%) fair in 3 (5.2%) white asphyxia in 10 (17.2%) blue asphyxia in 4 (6.9%), still-born in 1 (1.7%) and unclassified in 4 (6.9%) cases. The classification of the infants has been left to that one of the three sisters in-charge present at the operation. However it is worthy to note that of the above 58 infants 54 were stated to be normal within ten minutes of delivery. Further about 40% of these patients were suffering from conditions that were prejudicial to anaesthesia. These were divided as follows: Poxaemia 6 (10.5%) (of the total) A.P.H. 9 (15.8%), heart

conditions 5 (8.8%), chronic bronchitis 2 (3.5%), bronchiectasis 1 (1.7%), and spinal tuberculosis 1 (1.7%).

The state of the infant at birth in these cases was

Mother	Infant						
	Good	Satis	Fair	White	Blue	Died	Unknown
Toxaemias	2	2	0	1	1	0	0
A.P.H.	3	1	1	3	0	1	0
Heart	2	2	0	0	0	0	1
Others	1	0	1	0	0	1	0

It can be said that not one of the mothers showed any symptom that would point to trilene with nitrous-oxide being a dangerous anaesthetic for caesarean section. Their condition was recorded as good in 48, fair in 7, and unrecorded in 2 cases. Thirty-two mothers had some anaesthetic sequelae with headache in 3, nausea in 18, excess nausea in 1, vomiting once in 23 (none vomited more than once), and restlessness in 12 cases. One mother had post-operative bleeding—and she had had an A.P.H.—and she made a perfect recovery after a blood transfusion the amount of which is not unfortunately stated in the records. The premedication given to these patients was nearly always atropine 1/100 gr (0.65 mg) and strophanthin 1/200 gr (0.32 mg).

In direct answer to Mr Stern's assertions I can say that in this small number of cases there was no maternal death, no evidence of damage to either the nervous system or to the liver, and that not only was there no sign of damage to the conduction system of the heart, but that in the five heart cases operated upon not one was made any worse by the anaesthetic or the operation. Since the above dates, the majority of cases at this hospital have been dealt with in the same manner with similar results, but the records are not so readily available—I am, etc.,

Northampton

J STRUAN-MARSHALL

Ruptured Aneurysm of Right Auricle

SIR—The following condition is as far as I know, extremely rare. I am reporting it so that it will go into record.

A healthy man suddenly dropped dead in the middle of a minor fight with another man. The body was brought for post-mortem examination. On opening the chest the pericardium was found to be full of blood. This came from a ruptured aneurysm of the right auricle. The whole heart was removed and examined. In addition to the aneurysm of the right auricle there was dilatation of an already thinned ventricular myocardium. The valves and aorta showed no sign of atheroma, syphilis, or rheumatism. There was no fibrosis in the myocardium. The auricular myocardium had atrophied and in the thin aneurysm area there were only shreds of muscle over endocardium with abundant spaces of the latter not covered by muscle. The liver was enlarged to about three times its normal size. The man was about 30 years old.

I am not sure if ruptured aneurysm of the right auricle has ever been reported before. The specimen is now in the museum of the Kitchener School of Medicine, Khartoum—I am, etc.,

Juba Sudan

H ABDALLA

Shortage of Nurses

SIR—Your review of Dr James Barclay's book *Why No Nurses?* prompts me to write this letter. I have for many years looked after our nurses when sick, lectured to nurses served on hospital nursing committees and have been for some ten years an examiner in anatomy and physiology to the General Nursing Council. The position as regards nursing is very serious already and unless something revolutionary is done, is bound to get much worse.

It seems supremely unlikely that any of those at present organizing the nursing profession have the vision to do anything revolutionary. They still have the vocational complex plus plus plus. Now I am not going to suggest that matron's discipline should be relaxed. A nurse's work is very arduous, she is exposed to extra risks of ill health and she cannot be allowed to go racketing about half the night. However there are still some obvious means of improving things: (1) Nurses on the whole are not getting the 48 hour week or 96-hour fortnight. (2) It is mortifying for a qualified staff nurse

to find she is being paid at the same rate as a ward maid (3) The care of nurses is left far too much to matrons. The hospital committee should supervise the matrons' work by appointing at least one member of the medical staff and a lay member of the board and governors, who should meet the representatives of the nurses at least quarterly and hear their complaints and suggestions (4) Matrons should never be allowed to remain in one hospital more than five years.

These measures should lead to a gradual improvement, but drastic steps must be taken to rapidly increase recruitment. It is universally admitted that the hiatus between the school leaving age and the age that a girl can start nursing loses thousands of recruits yearly. A girl who is earning a good wage and has regular hours and freedom after work is not likely to take up nursing and its restrictions. Only the very keen and the relatively unemployable will become recruits. Apropos of the latter it would be incredible, if one had not suffered it for years, how large a percentage of the candidates for the Preliminary Examination ought never to have been accepted as probationers. Their chances of ever qualifying are nil, and they are only fit for the most menial jobs. One cannot blame the matrons who accept them, it is that or nothing. One cannot blame their tutors, they are unteachable.

Now there is an obvious remedy. It is an expensive one, but nurses are essential. I would insist that from the earliest school-days girls are interested in nursing, one or two hours a week they dress up in nursing uniform with a red cross, and are given bandaging lessons with dolls and lessons in bed-making, etc. As they get older they would have lectures explaining to them how being nurses would teach them personal hygiene cooking for the sick, preventive medicine, the care of their children, etc. In their pre-leaving years they would be examined. Successful candidates leaving school at 15 would become paid pupils of the State and attend special schools. They would pass examinations each year and be eliminated and passed on for another year.

Before they reached their eighteenth year they would have passed their Preliminary Examination and would enter on their hospital duties proper completely untrammelled by the subjects of anatomy, physiology and hygiene and would be able to concentrate at once on real nursing. I submit that on these lines the nursing profession would be reborn and over subscribed—I am, etc.,

LEONARD LEY

Sarcoma in Intra-abdominal Testis with Torsion of Pedicle

SIR—I was interested to read the report of Drs A H Bennett and W G Shaw (Feb 15, p 256) of a case of ectopia testis with seminomatous change and torsion. The coincidence of the triple pathology must be very rare. I am therefore prompted to record an almost exactly similar case that I encountered in 1931 in Singapore. Unfortunately my notes of the case were lost owing to the Japanese occupation of the country, but the facts briefly were these.

A young adult male was admitted with abdominal pain of sudden onset and no testis was present in the right side of the scrotum. Laparotomy showed a haemorrhagic peritoneal exudate and a dark plum coloured globular tumour the size of a fist with tightly twisted narrow pedicle arising from the right side of the pelvis. It looked exactly like a twisted ovarian cyst. Excision. Recovery. Later history unknown.

The pathologist's report in this case stated that the tumour was a sarcoma in an intra abdominal testis with torsion of the pedicle—I am, etc.,

London S.W.1

Persistent Anaemia in a Breast-fed Infant with Erythroblastosis Foetalis

SIR—It is worth while underlining Dr Rosemary Davies's case report published in your issue of Jan 25 (p 138). I will be absolutely brief in deference to your inevitable shortage of space but the point in question is by no means well known. Eighteen months ago I also saw a child born jaundiced with erythroblastosis foetalis. Transfusions had to be continued owing to persistent fall in the red cell count until at the age of two months the breast milk was tested and found to contain anti-Rh agglutinins. Cessation of breast-feeding brought the haemolysis and the need for further transfusions seven having been given to an abrupt end—I am, etc.

Edgware Middx

F HARWOOD STEVENSON

Obituary

G O LAMBERT, M.D., F.R.C.P.

Dr Gordon Ormsby Lambert, of Reading died at the age of 69 at Bucklebury, Berks, on Jan 26 after a short illness. He had had an active and distinguished career and had only recently retired from practice. Educated at Lancing and at St John's College, Cambridge, where he took his B.A. degree in 1898 he completed his medical training at Charing Cross Hospital, qualifying M.B., B.Ch. in 1901. After holding various house appointments at his own and at other hospitals he came to Reading early in the present century, and proceeded M.D. in 1906. He was appointed medical registrar to the Royal Berkshire Hospital in 1913, assistant physician in 1914, and physician in 1923. In 1942, after being senior physician for many years, he was elected F.R.C.P. The same year he retired from the active staff of the hospital though still holding the post of cardiologist and was made a consulting physician. His private practice however he continued until his recent retirement. Dr Lambert's services were much in demand in the district as a consultant in medicine of which he had a very wide knowledge. He was a good diagnostician and most conscientious over his work, which he took very seriously, no one could have surpassed him in the thoroughness of his examinations. He rarely missed anything. Some may have thought that occasionally his treatment was rather overabundant in its many details, but it was based on scientific reasoning and he was in no wise biased against surgical assistance, if he thought it necessary or even remotely helpful. He had a most unselfish character and was always kind and considerate. Dr Lambert contributed a number of articles to the medical press chiefly on cardiac conditions in which he was particularly interested. He was at one time joint editor of the Royal Berkshire Hospital Reports. Philosophy also attracted him, he was the author of a booklet recently published entitled *Happiness in a Modern World*. He was twice president of the Reading Pathological Society and had been a member of the British Medical Association since 1912. He was president of the Reading Division in 1931-2. In addition to his professional work he at one time took some part in local politics and was for four years a member of the town council. It is sad to think that after so long a time spent in the service of others Dr Lambert should not have been spared to enjoy the quiet country life that he had looked forward to and had only just begun to taste.—W.B.S.

JOHN WALLACE OBE, M.B., C.M.

By the death of Dr John Wallace on Feb 13 Weston super Mare has lost its oldest medical practitioner. Dr Wallace was born in Fife in December, 1856 and although in his ninety first year he was such an exceptionally vigorous man that he was able to continue his practice and other interests until a few days before his death. While he was a first year student at Edinburgh University his father died suddenly and young Wallace had to return home to manage the family farms. He remained engaged in farming and stock breeding and raising until 1885 and to learn business methods he served a year in the office of a chartered accountant in Edinburgh. In 1886 he married and with his wife spent two years in Italy, Germany and France studying forestry and dairy farming.

It was not until he was 30 that he decided to take up again the study of medicine. He was probably influenced in this decision by his younger brother—afterwards Sir David Wallace and a well known surgeon in Edinburgh—who had already qualified. He returned to Edinburgh University graduated M.B., C.M. in 1892 and obtained the B.Sc. (Public Health) in the following year. After a period as assistant to Sir Henry Littlejohn the medical officer of health for Edinburgh further study at Berne and some mental hospital experience Dr Wallace settled in medical practice in Weston super Mare in 1896 over fifty years ago. Here he quickly became a trusted family physician but so great was his tireless energy and versatility that he successfully developed many other interests.

BRONCHIAL ASTHMA

The effect upon the bronchial musculature is among the selective mechanisms of action of the drug Cardophylin. It appears that the seat of its bronchial antispasmodic action is peripheral and due to direct depression of bronchial smooth muscle.

For sustained control of gastric hyperacidity

NOVASORB

(Hydrated Magnesium Trisilicate)

Novasorb provides for sustained control over gastric hyperacidity without producing an alkaline condition in the stomach. It thus presents a desirable improvement over the older antacids, where control is limited to the immediate reaction and where continued administration of excess alkali may induce alkalosis.

High adsorptive properties

Will not give rise to alkalosis

With suitable doses, does not destroy
peptic activity

A safe antacid for general use

The Novasorb brand of hydrated magnesium trisilicate was developed and introduced by Evans Fine Chemical Works and is based on original observations and clinical trials (Brit med J 1936 1, 143 205 and 254).

Radiostol is calciferol in its purest form, it is suitable, therefore, for administration in the large doses necessary in the treatment of lupus vulgaris and arthritis. Calciferol itself is not entirely free from undesirable properties when given in the huge doses frequently recommended but it is essential that it should be entirely free from the more toxic products of irradiation.

Radiostol is issued in capsules each containing 50,000 i.u. (for use in the treatment of lupus vulgaris) and in solutions containing 100,000 and 200,000 i.u. per gram respectively (for use in the treatment of arthritis). Radiostol is available also in solution (Liq. Calciferolis B.P.) and in pellets each containing 3000 i.u. for the prevention and treatment of rickets.

**DICOUMARIN
(DICOUMAROL)**

A synthetic anticoagulant which depresses the blood prothrombin level

For the prophylaxis and treatment of thrombosis and embolism, particularly after operations—

- Puerperal thrombosis and thrombophlebitis
- Coronary thrombosis and pulmonary embolism
- Cavernous sinus thrombosis
- Post-traumatic arterial thrombosis

Q19 Telegrams DUOCHEM WESDO LONDON

He had an eminently legal mind and much financial ability—probably family traits, for one of his brothers established a well known law firm in Edinburgh and became a director of the Bank of Scotland. For several years he was deputy to the coroner for North Somerset, and because of his extensive knowledge of medico-legal problems he was often consulted by his medical colleagues. He was a past president of the Bath and Bristol Branch of the British Medical Association, of which he had been a member for over fifty years. He opposed the medical provisions of the National Health Insurance Act of 1911, and was one of those medical men who interviewed Mr Lloyd George on the subject. In 1911 he became medical officer of health for the urban district, and held this part-time office until 1929, when he was 73 years old. He did valuable work in connexion with the water supply, a new infectious diseases hospital, the erection in 1916 of the first public abattoir in the county, and the formation of the Tuberculosis Care Committee, of which he was chairman.

Dr Wallace took an early and active part in Somerset's pioneer campaign for the control of mental defectives and the provision of a farm colony in the county, when the Somerset Committee was formed in 1914 he was co-opted as an expert member and remained a member for the rest of his life. His mental hospital and business experience led to his help being sought on the management committees of the various institutions as they were developed. From 1924 to 1946 he acted as medical visitor to the visiting justices for the private mental hospitals and institutions in the north of the county. When a voluntary war hospital was opened here during the first world war, it was placed under his direction, and he was deservedly awarded the OBE for his distinguished services. During the recent war, when well over 80 years of age, he acted most efficiently as war emergency hospital officer for the area. As a business man he took a practical interest in the Moorland Sanitary Steam Laundry and was chairman of the directors at the time of his death.

He was a great sportsman and his many hobbies included fishing, shooting, archery, beekeeping and golf. In his earlier years he was a scratch golfer and one of the founders and a past president of the Weston-super-Mare golf club. It was only comparatively recently that he gave up playing regularly there. He was truly a hardy Scot, and although he started work early and kept up to date by reading till the small hours, he was never known to be tired. Dr Wallace had a forceful and colourful personality, and though some thought him a little austere he was really the kindest of men, a much sought-after adviser, and in secret very generous to the needy and deserving.

JOHN B H HOLROYD MRCS

Dr John Brook Henderson Holroyd, who died in Sheffield on Feb 8 at the age of 68, was a well known figure in the medical life of the city. He entered the Sheffield Medical School in 1905, and qualified MRCS, LRCP in 1910. He held a number of house appointments before settling in general practice in the Pitsmoor district of Sheffield.

He served in India and elsewhere as a captain, R A M C, during the 1914-18 war. Dr Holroyd had always been attracted to the administration of anaesthetics, and early in his career became one of the visiting anaesthetists to the Royal Hospital in Sheffield and was later attached to the Royal Infirmary in the same capacity.

In order to arouse the interest of the medical students in the study of anaesthesia his offer of an annual prize in the form of a gold medal was accepted by the faculty of medicine. The medal was awarded on the results of a competitive examination in the theory and practice of anaesthesia. Dr Holroyd was one of the original members of the council of the Society of Anaesthetists at its inception in 1935 and was given the diploma. In 1942 he resigned from general practice and devoted himself solely to anaesthesia.

During the recent war he gave valuable service to the E M S as an anaesthetist and from October, 1939, to September, 1945, he acted as temporary lecturer in anaesthesia in the University of Sheffield. He devoted his energies unstintingly to the instruction of students in this important branch of their work. He also instituted the arrangement whereby every new resident at

the Royal Sheffield Infirmary and Hospital had to give anaesthetics under the supervision of one of the honorary anaesthetists before being allowed to take a case entirely on his own. This arrangement has always been welcomed by new residents whatever their school.

With Jack Holroyd in charge of the anaesthetic, the surgeon's anxiety on that score was eliminated. He always gave due warning as to what might be attempted with safety and always carried on quietly and efficiently, starting all anti-shock therapy without bothering to wait until it was suggested to him. He visited each patient for a day or two subsequently and treated any complication due to the anaesthetic so far as he could. The relationship between him and the surgeon with whom he had worked for twenty-five years was a happy one. Each had the full confidence of the other. He was keenly interested in the development of anaesthesia and was always well abreast of the recent advances. He will be sadly missed by his colleagues.

The attendance at the service held in the chapel of the Royal Infirmary on Feb 12 testified to his popularity as an anaesthetist and a man. For the last few months he had been ailing, but it was not until three weeks before his death that he gave up his work, quoting his favourite aphorism to one who had worked with him for many years: "It's a wise man who knows his own limitations."

W H DE B HUBERT, MRCP

The premature death of Dr William Henry de Barge Hubert has robbed psychiatry of an unusual personality and one of its most astute clinicians. Hubert received his training in the specialty at the Maudsley Hospital under the late Prof Mapother, who made no secret of his high opinion of Hubert's abilities and his belief that he possessed 'a touch of genius'. In 1934 he was appointed chief assistant to the department of psychological medicine at St Thomas's Hospital, and after four years of outstandingly good work there was promoted to assistant physician in the department. About the same time he published, with Dr Norwood East, a report upon the "Psychological Treatment of Crime," embodying the results of four years' investigation of this subject at Wormwood Scrubs.

On the outbreak of war he at once joined the R A M C and very shortly succeeded in joining his chief, Dr Henry Yellowlees, who was already in France as consulting psychiatrist to the B E F. After the fall of France Hubert went to North Africa, where he spent more than three years, first as medical officer in charge of a division of the 41st General Hospital, and finally as adviser in psychiatry with the rank of lieutenant colonel. His health suffered grievously under the stress and strain of those years and the rest of his life from his return to civilian work in 1945 until his premature and tragic death on March 5, was a struggle against illness the extent of which few of his friends realized. In addition to all the difficulties and anxieties of taking up the threads of civil life and work again and rebuilding a consulting practice he had much insomnia, repeated bouts of malaria, and in the autumn of 1945 an attack of coronary thrombosis. He remained cheerful and optimistic to the end, he was never heard to grumble or complain, and even when his state of health forced him to resign his post on the staff of St Thomas's, only a few weeks before his death he still looked forward to an active and busy life as a consultant.

In his early days Hubert had leanings to the Freudian school, but he forsook it because he thought it lacked practical relationship to the clinical work to which he was devoted. Child psychiatry became one of his special interests. As a shrewd diagnostician after a first interview with any psychiatric patient he had few equals. He had, perhaps unfortunately, a very large share of the artistic temperament. Anything humdrum or mechanical was an abomination to him and he found the routine and business side of a consultant's life something of a weariness. As an assistant and a junior colleague he was unsurpassed, by reason of his splendid loyalty, his unflinching good humour, and his astonishing readiness and resource. In more independent positions he tended to become the somewhat impractical dreamer, but remained always a most charming companion with something intelligent well informed and thought-provoking to say on almost any subject. He had many interests outside medicine. He was well up in astronomy.

played a good game of chess, and was a water colour artist above the average. He had a most disarming quiet friendliness of manner, and though he was not afraid of giving his opinions on controversial points, did so with such tact that he made very few, if any, enemies. But it was with individual patients that he was at his best by far, and it is as a loyal, cheerful colleague with a remarkable clinical flair that his friends will remember him.

Dr DUNCAN MACDONALD died in Oban on Feb 16 at the age of 74. Dr MacDonald was the sole survivor of a family of ten. On his father's side he belonged to the MacDonalds of Dunnyveg and the Antrim Glens, while on his mother's side he was a great-great-grandson of James MacDonald of Skye, who was a brother of Allan MacDonald of Kingsburgh, the husband of Flora MacDonald. Duncan MacDonald qualified M.B., C.M. in 1893 at Glasgow and proceeded M.D. in 1905. After two years in the County of Durham he was appointed medical officer for Torosay, Mull, where he remained for six and a half years. Dr MacDonald went to Oban in 1901 in succession to Dr MacKellvie and was largely instrumental in the founding of the county sanatorium there. He resigned his office as medical superintendent of the sanatorium early in 1943 after thirty four years of devoted service to his patients. He also served on the staff of the West Highland Cottage Hospital, and during the first world war he was the honorary medical officer of Dungallon Red Cross Hospital at Oban. In 1943 his fifty years of practice was celebrated by a public presentation and a dinner. He retired a year later. Dr MacDonald is survived by his wife and two sons.

Lieut-Col JOHN DU PLESSIS LANGRISHE died in Edinburgh on Feb 28, at the age of 63. A grandson of the Rev Sir Hercules R. Langrishe, of Knocktopher, Co. Kilkenny, he graduated in Dublin in 1906. He was awarded the D.S.O. in 1918, by which time he had had 12 years' service with the regular R.A.M.C. He commanded a field ambulance during the last two years of the war and was mentioned in dispatches. He took the D.P.H. in 1920 and thereafter served as D.A.D.H. in the Bermuda Command for three years, and at Catterick for a further three years. Leaving the Army in 1928 he became lecturer in the public health department of Edinburgh University. In his time a "rugger blue" and a very fine oar, he always actively supported the university team and crews.

The Services

The Queen of the Netherlands has bestowed the decoration of Officer in the Order of Orange Nassau upon Surg. Lieut. Cmdr. C. G. Roworth, R.N.V.R., for outstanding services as senior medical officer, Anglo Dutch Sick Quarters, Holyhead.

The following decorations have been bestowed by the King of Norway: King Haakon VII Liberty Cross, Surg. Capt. J. C. Souter, R.N., for services rendered to Norway during the war; King Haakon VII Liberty Medal, Surg. Cmdr. J. A. Kerr, R.N.V.R., for outstanding services in connexion with the liberation of Norway; Surg. Cmdr. W. Flynn, R.N., for services rendered to Norway during the war.

Major (now Temp. Lieut.-Col.) J. B. Bishop, R.A.M.C., has been awarded the Efficiency Medal (Territorial), 1st Class.

Major (Hon. Lieut. Col.) R. G. Evans, M.B.E., Capt. (now Temp. Lieut.-Col.) J. B. Bishop, and Lieut. (Hon. Capt.) I. R. Rosekilly, R.A.M.C., have been awarded the Efficiency Medal (Territorial).

DEATHS IN THE SERVICES

Col. HARRY MALCOLM MACKENZIE, C.I.E., Indian Medical Service, retired, died on Feb. 25, aged 69. He was educated at Larchfield School, Helensburgh, at the Royal High School, Edinburgh, and at Edinburgh University, where he obtained honours in the M.B., Ch.B. examination in 1899. He entered the Indian Medical Service in 1900 and took the D.P.H., Cambridge, in 1903. Most of his service was in the North-West Frontier Province and in the Punjab. He saw active service throughout the War of 1914-18 and was awarded a star and two medals. In 1914-15 he went to Egypt on the hospital ship *Hardinge*. He was promoted to full colonel in 1929. In 1931-2 he held the important post of surgeon to the Viceroy and in the latter year was awarded the C.I.E. for his long and distinguished service. He published articles of medical and scientific interest in the *British Medical Journal* and had been a member of the British Medical Association since 1901. His recreations included golf, fishing and shooting. He married Elfreda, daughter of A. A. Hudson, K.C. and had a son and a daughter.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

The honorary degree of D.Sc. was conferred on Sir Edward Mellanby, B.C.B., M.D., F.R.S., Secretary of the Medical Research Council, in Congregation on March 15.

The following medical degrees were conferred during February and March:

M.D.—G. F. Barran, E. D. H. Cowen, J. F. Stokes, D. M. Baker, J. S. A. Doran, P. H. Willcox, G. H. Wooler, J. C. Waterlow, M. A. Rugg, Gunn, J. Aspin, A. P. Dick, C. C. Thomas.

M.B., B.Chir.—R. H. B. Mills, *M. E. E. White, *A. P. Baker, *D. O'Brien, *J. A. S. Forman, *T. C. L. Parry, *R. Marshall, *D. J. Watt, *A. Pines, A. G. Norman, *G. T. F. Braddock.

* By proxy.

Joseph Marks, M.B., B.S., and Edward Derek Huxley, Cowen, M.B., B.Chir., have been elected to Frank Edward Elmore Fund studentships from March 1.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

A series of lectures in anaesthesia will be delivered at the College (Lincoln's Inn Fields, W.C.) from April 14 to 18 and April 21 to 25 at 6.15 p.m., and on April 28 and 29, at 5 p.m. The fee for the whole course is £5 5s., Fellows and Members of the College and Licentates in Dental Surgery will be admitted for £3 3s. Applications and cheques should be sent to the assistant secretary of the College. Details of the lectures will be published in the diary column of the *Supplement* week by week.

At an ordinary meeting of the Council, held on Feb. 13, with Sir Alfred Webb Johnson, Bt., President, in the chair, Prof. Louis Bazy, of Paris, attended and was enrolled as an Honorary Member of the College.

The Hallett Prize for Anatomy, Applied Physiology and Pathology was awarded to H. J. Richards (University of Sydney).

Prof. F. Wood Jones was appointed Arms and Gale Lecturer and Dr. R. J. Last and Mr. H. F. Lunn, Amott Demonstrators.

Sir Cecil Wakeley was appointed chairman of the editorial committee appointed to control the publication of the forthcoming *Annals of the Royal College of Surgeons of England*.

Diplomas of membership were granted, jointly with the Royal College of Physicians of London, to P. J. Horsley, F. S. Huxley, and to the 96 successful candidates whose names were printed in the report of the meeting of the Royal College of Physicians of London in the *Journal* of Feb. 15 (p. 276).

Diplomas in Public Health were granted, jointly with the Royal College of Physicians of London, to the 32 successful candidates whose names were printed in the report of the meeting of the Royal College of Physicians of London in the *Journal* of Feb. 15 (p. 276).

Diplomas in Laryngology and Otolaryngology were granted, jointly with the Royal College of Physicians of London, to W. F. Dickie Clark and R. T. Raymond Jones.

The Council of the College invite applications for annual examinations for the Fellowship for the Licence in Dental Surgery, and under the Examining Board in England. Particulars and forms of application, which must be returned completed by March 31, can be obtained from the assistant secretary.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

At a quarterly meeting of the College, held on Feb. 4, with the President, Dr. D. M. Lyon, in the chair, Drs. Henry James Parish (Pettis Wood, Kent), Robert Carmichael Wood (Edinburgh), and John Alexander Malloch (Edinburgh) were introduced and took their seats as Fellows of the College. Dr. William Alexander Liston (Edinburgh) was elected a Fellow of the College.

Drs. John Morton Henderson (Edinburgh), Nawab Ali (Beneal), Sujata Chaudhuri (Calcutta), Isidore Schrire (London), James Parlange Baird (Glenbuck), Charles Groves (Edinburgh), William Hunter (Edinburgh), Jacob Du Toit (Pretoria), Ralph Lulu Tobias (Cape Town), Andrew Campbell Watt (Edinburgh), Hamidali Mahbubali Khan (Poona), Roland William Riddell (London), Vera Sarah Emanuel (Johannesburg), Cecil Harris (Troon), Harland Cornelius Hastings (Edinburgh), and Alastair Robert Currie (Glasgow) were elected Members of the College.

ROYAL COLLEGE OF SURGEONS IN IRELAND

A postgraduate course in surgery will be held at various hospitals in Dublin on Mondays to Fridays during the eight weeks April 14 to June 6 beginning at 12 noon each day. Attendance at the

course, the fee for which is £21, will be strictly limited to 30 Registration may be made for either half of the course, at a fee of £10 10s, on application to Prof N Rae, D Sc, registrar of the College, St Stephen's Green, Dublin

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At a meeting of the Council, held in the College House on Jan. 25, with the President, Mr William Gilliatt, in the chair, I B Ewart and G J St C Fisher were admitted *in absentia* to Membership of the College

The following candidates were elected to the Membership of the College: D Ballantine, Margaret R Biggs, W S Campbell, H V Corbett, J B Cochrane, S J Cohen, G L Daly, A Davis, J R Dickinson, Bessie Dodd, Morag Dods, I Donald, R C Gill, Jean L Hallum, A J Hardy, R F Lawrence, T H Lawton, J M McBride, R A E Magee, Eileen C Miller, J D Murdoch, M K O'Driscoll, S S F Pooley, L J Quinn, Kathleen M F Worrall, J L Wright

Medico-Legal

AN OVERDOSE OF NEPENTHE

The East Surrey coroner, Dr F J Baron, recently inquired* into the death at Wimbledon of a girl child of 13 months. She had been suffering from severe mastoiditis and had died in hospital on the day she was admitted. Dr D Haler, the pathologist examining for the coroner, said that death was due to the mastoiditis, but a suggestion was made by the relatives that it had been accelerated by nepenthe, which they alleged had been prescribed in excessive dosage by Dr Loiza Elwell-Johnston.

Dr Haler at first stated that he did not think the drug had accelerated the death, but later admitted that he could not exclude the possibility. The mother said that the child had sickened on Dec 31, 1946, and that Dr Johnston had attended and brought in Dr J G Lessey as a consultant. He had prescribed 'M and B' tablets, and as he was about to leave he had remarked, 'You might give her a little nepenthe. It will help her to sleep.' When the drug arrived the mother administered some in water in a teaspoon but the child vomited. She also gave half a tablet of 'M and B'. As the baby continued to be restless she gave it a teaspoonful of the nepenthe in water. The baby then became very drowsy and seemed somewhat peculiar, so she telephoned to Dr Johnston who ordered the child to be placed in a hot bath. The infant collapsed and was later removed to hospital where she died.

Dr Johnston said in evidence that she had written two prescriptions. One, produced in evidence, stated the dose as a teaspoonful and was inscribed as for 'Janice Shelley'. The other, which she supposed she had torn up or put in her pocket, had been made out for 'Query half a teaspoonful in water. She had not known the exact official dose. Dr Lessey had said the dose was small, and she had expected the chemist would know and would check it. The prescription for 'M and B' had been inscribed 'Mrs Shelley for Baby Shelley'. Dr Haler agreed with counsel for the relatives that a teaspoonful for a child of 13 months was a gross overdose, the correct dose being two or three drops, but said that children went rapidly downhill with mastoid infection and the baby could not have been saved.

Mr R J Cann, who examined the body for the relatives and gave evidence at an adjourned hearing, said he would have thought the overdose of nepenthe was the cause rather than the toxic absorption from the ears. He had only examined the ears, however, and made no claim to be a pathologist. The coroner found that the overdose was at least an element in the causation of death in some degree and the prescribing of it must be regarded as evidence of negligence but not criminal negligence. His verdict was that the child died of bilateral mastoiditis accelerated by the overdose of nepenthe.

Readers will recall that Lord Hewart, the Lord Chief Justice, said in *R v Bateman* (1925) that between civil and criminal negligence there is a difference both in degree and in kind, it is negligence which shows such disregard for the life and safety of others as to deserve punishment.

* Wimbledon Borough News Jan 17, 1947

Medical Notes in Parliament

SCOTTISH HEALTH SERVICE BILL

The Standing Committee on Scottish Bills considered on March 4 Clause 32 of the National Health Service (Scotland) Bill.

Mr J S REID said the Clause was merely a skeleton of the general medical services which must be filled out by regulations. He asked Mr Westwood to tell the Committee the date on which he expected these regulations to be introduced. The doctors must see the regulations in good time if they were to have a fair chance of deciding whether to come into the scheme.

Mr WESTWOOD said many regulations would be made under this Clause and it was right that the doctors and the House should know them at the earliest moment. He hoped to issue the regulations six months before the scheme came into operation. There would have to be discussions with the medical profession and the Government also expected the House to consider the regulations. The Clause was ordered to stand part of the Bill.

Doctors Entering the Scheme

On Clause 33 Mr REID moved to leave out in subsection 1 which deals with applications by medical practitioners to be included in the list of practitioners undertaking to provide general medical services, the words 'before the appointed day'. Mr Reid said the committee had not been told why a doctor was not allowed to come into the scheme beyond the appointed day without permission. He could see no practical reason for this restriction. On the other hand there was a good political reason. The Government would hold a pistol at the head of a doctor and would tell him 'you have either to come in at once or you may risk the loss of your livelihood'. That was not a fair way to address the medical profession. What possible reason could there be for saying this to a doctor in an under-doctored area? Was any area in Scotland so over-doctored that the Government wanted to eliminate some of the existing practitioners?

Mr WESTWOOD said the Clause clearly restricted the right of doctors to apply to come into the scheme after the appointed day. If any doctor could at any time come into the scheme after the appointed day, he would have the right to secure automatic participation in the medical service wherever he decided to serve. Mr Westwood said he understood the amendment was to enable a doctor to choose an area in which he wanted to serve. That would defeat the Government's object of controlling the distribution of doctors.

Mr REID said the amendment would only give the doctor the right to come in where he already was.

Mr SCOLLAN raised the case of a village which received medical services from an adjoining county town. If a doctor opted to come into the scheme for his patients in the village, could he carry on his private practice in the burgh?

Mr WESTWOOD replying to further remarks by Mr Reid, said that he could not promise consideration to any amendment which was intended to allow an individual to remain out of the Service as long as he liked. It would be impossible for the Secretary of State to know whether an area was under-doctored or over-doctored if certain doctors did not come into the Service on the appointed day. The difficulty envisaged by Mr Scollan would not arise, because the Executive Council would deal with the whole of the county.

Col ELLIOT continued the discussion of Clause 33 by moving a new subsection to ensure that regulations under the Clause should provide for requiring the Scottish Medical Practices Committee to determine the number of medical practitioners to provide an adequate service in each area or part of an area and for publication of the number of medical practitioners so determined for each area or part of an area. He said that to leave in the discretion of a committee of five as the Bill did a power to refuse one person and select another on the ground of adequacy for which no definition existed except in the minds of that committee was not in the public interest. There was a much more even distribution of doctors in Scotland than in England. It should therefore be possible to make some list by which the doctor desiring to move from one part to another or the medical student taking up practice would have an indication where an application was likely to be favourably regarded by the Medical Practices Committee.

Mr WESTWOOD could not accept the amendment. It would make the scheme too rigid.

Mr REID observed that if Mr Westwood said the adequacy of the doctors in an area could not be determined by counting their heads then the Bill was wrongly drafted.

Mr BUCHANAN said he did not wish to be bound by a list of doctors in areas for five years. He instanced Fife Mining where there must be considerably extended in the next few years with a population of many thousands more and the number of doctors must be increased accordingly. It was no use publishing a document unless it could convey something to the public, but he promised that he and Mr Westwood would look into the matter again. Col Elliot withdrew his amendment.

Freedom of Movement Restricted

On the motion that the Clause stand part, Mr REID said that, if it went through, medical men would be practically the only persons in the country whose freedom of movement was restricted. Where was the overwhelming necessity to act toward doctors in a way which Parliament had given up with regard to everybody else? On the English Bill it had been contended that the discrepancy between the number of doctors in different areas was such that the interests of the public could be safeguarded only by restricting the movement of doctors. The Opposition had not accepted that in England, but there was an infinitely stronger case for it there than in Scotland. In England the House had found a number of cases where there were more than 3,000 per general practitioner. That was not found in Scotland. There were only thirty-odd areas in the Scottish list which seemed under-doctored. Greenock was the only one where the number of persons per doctor was over 3,000. In that town there were twenty-three general practitioners, and another half dozen would bring Greenock well up to average. Was Parliament to impose this restriction on the whole of the medical profession to attract half a dozen doctors into Greenock? The thing could be done by differential salaries. The county of Angus was not too well doctored, but probably because a number of doctors in Dundee practised outside the city boundaries. Half a dozen more practitioners in that county would get it nearly up to the average. In West Lothian there were about twenty-seven practitioners, and the average figure for a practice was about 3,000. Very probably another ten doctors were required there, but was that a reason for setting up an enormous administrative machine? Avonshire, Lanarkshire, Glasgow, Renfrew were all round about the average of 2,500 per practitioner and required some more practitioners, but could not be called grossly under-doctored. Under the Clause conundrums would crop up continually.

Position of Assistants

Mr WILLIS asked for a statement on the position of the paid medical assistant under the Clause. Would he be free to make application to be included in the list of medical practitioners?

Sir WILLIAM DARLING said that if there was an undesirable area which could not acquire doctors in the ordinary way, a press gang the Scottish Medical Practices Committee, would get hold of eight or ten unwilling doctors male or female, black or white and drag this herd of conscripts into an area where they did not want to go. What would be the effect upon the sick and ill in that particular area?

Mr WESTWOOD said the paid assistant would have no title to be included in any particular list but would be free to set up practice on his own in any particular area. He could ask to be put on the list in the area in which he was an assistant, but if it was already fully doctored he could not set up in that area. If he remained an assistant his participation in the Service would be covered by the regulations which were to be made.

Mr RANKIN asked whether an assistant who, before the passing of the Act was under covenant with his doctor not to enter into professional service in the area in which he acted as an assistant would be freed from that covenant by the Act.

Mr WESTWOOD said full details would be worked out before the regulations were issued and there would be consultation with all the interests affected. If the Bill abolished the sale of practices machinery had to be found for determining how vacancies could be filled and Clause 33 provided that machinery. It was true that the variations in the "amount of personnel" in Scotland were not so great as in England. The highest ratio of general practitioners per head of the population just over 1,000 per doctor was found in Argyllshire and was due to the scattered nature of the countryside. The only area before the war in which it was suggested that there was a substantial degree of over-doctoring was Edinburgh where the 312 general practitioners represented one for every 1,500 of the population. The idea in the Clause was contained in the White Paper issued by the Coalition Government in 1944. This had stated that an unrestricted right to any doctor to enter into new practice and

there to claim public remuneration would make it impossible to fulfil the new undertaking to ensure a service for all.

The question that the Clause stand part of the Bill was then put and carried by 26 to 9.

Sale of Doctors' Premises

Mr REID moved to leave out subsection 3 of Clause 34. This subsection deals with the sale or letting by a medical practitioner or his personal representatives to another medical practitioner of premises previously used by the first practitioner for the purpose of his practice and for a similar use by the second practitioner where the consideration for the transfer is substantially in excess of that which would be expected if the premises had not previously been used for medical practice. Mr Reid said Clause 34 raised extremely technical points. He suggested that in the subsection the word "knowingly" had been put in the wrong place and did not read as it should that the vendor "knowingly accepts a price above what was reasonable." Therefore an offence could be committed by a person who in good faith sold his house to a new doctor at a price which was later determined to be substantially in excess of what might reasonably be expected. The determination of a reasonable price would not be made by the seller or by the purchaser, or by any individual the seller could consult, but by some judicial authority six months or a year later. Land valuers often differed in their estimate of prices and a man's freedom would be imperilled because six months earlier a land valuer had said that a certain price was reasonable. How did the Government propose to draw an indictment in such a case? Was it prepared to put into the indictment the price which might reasonably have been expected? If not, a fair notice would not be given to the accused of the case against him. The last part of the subsection said that where there had been a composite transaction a court was to sort that out. Did that mean the judge or the jury?

When the Committee resumed on March 5 Mr Reid concluded his speech and the Lord Advocate (Mr G. R. THOMSON) replied.

The Lord Advocate said the general idea of Clause 34 was to prohibit the sale of goodwill by any medical practitioner who fell in with the scheme. In subsection 3 an attempt was made to prevent a black market in the sale of goodwill. One of the most obvious ways in which the sale of goodwill could be got round was by giving an inflated price for medical premises. The substantial danger arose from the sale of premises that had been used by the doctor, and it was essential to have a subsection of this kind in the Bill. The subsection said that if a medical practitioner was going to dispose of his premises for the purpose of a practice—this meant he had to know to whom he was selling and to know the purpose of the sale—and it turned out that the price was substantially in excess of what might have been expected for the premises, then that was a sale of goodwill. He saw no difficulty in putting this into an indictment. If the vendor knew the sale was to a doctor to enable the other practitioner to use the premises for the purpose of a practice then the vendor was bound to be on his guard and after that the question of price was entirely a matter of evidence. It would be intolerable if the Crown had to prove that a seller knew the price was substantially in excess of what the premises were reasonably worth, or if a man could go to his solicitor instruct him to carry out the sale and then say, when challenged, "I never knew what the position was. I left it in the hands of my solicitor." If the vendor was apprehended he could not complain because there were ample safeguards in the Clause. The vendor could go to the appropriate authority and get a certificate that the thing was in order. The last sentence of the subsection which provided for an apportionment by the court of the consideration paid was necessary. If premises and a motor car were sold the court would be able to say that a fair price for the car would be £500. He saw no difficulty in working this out so far as the court was concerned. The judge might say there was not sufficient evidence but on the question of guilt the final decision must be with the jury.

Mr SPENCE asked who was to lay the information of an alleged fraud. Was that to be done by an informer, or by the Executive Council in the area, or by a new army of "snoopers"?

The LORD ADVOCATE said anyone to whom knowledge of an offence came was entitled to go to the Procurator Fiscal and tell him about it. No special machinery was intended.

Mr MCKINLAY asked what precluded the employment of ordinary valuation machinery in the transfer of property.

The LORD ADVOCATE said Mr MCKINLAY's idea was that it would be sufficient to constitute an offence if the sum paid was substantially in excess of the valuation by the district valuer. The Lord Advocate saw the force of that, but thought it better

to leave the matter to a jury. The district valuer could be a Crown witness. The mere submission of a figure to the registrar might not reveal the whole facts. There were all kinds of methods of getting information and the whole thing was left to the ordinary law. What the Government had to get at was the case of a man who set out to sell his premises at a price which was substantially in excess of what those premises were worth in the open market and did so with the idea of getting money for the goodwill. That would be contrary to the law, and it would not be desirable to insert the words 'known by him to be in front of the word substantial'. That would put a premium on the ignorance of a man who deliberately kept away and left it to somebody else to know about the figure. In drawing an indictment his inclination would be not to put in the figure.

Mr WESTWOOD hoped the Committee would come to a decision. The purpose of the Clause was to prohibit the sale of practices and the Government was not retreating from that. He had not the slightest intention of allowing any subterfuge to be used. The Opposition were more interested in the price to be got for the property of a doctor who was going out of business than in looking after the doctor who was to come into the business. Mr Westwood did not wish the incoming doctor to be overburdened with debt. In the past because of the sale of practices many doctors had been more worried about the loans by which they purchased their practices than concerned with their work. Mr Westwood moved that the question be put. This was carried by 25 to 15 and Mr Reid's amendment was defeated by 27 to 15.

"Irrespective of Goodwill"

Mr WESTWOOD then moved to vary subsection 3 in respect of the definition of an excessive consideration for the sale, letting, or other disposition. In place of the reference in the subsection to a price which could reasonably have been expected if the premises had not been previously used for the purposes of a medical practice, he moved to insert a reference to the price which might reasonably have been expected "to be paid by a medical practitioner for the premises as such irrespective of goodwill". He said the amendment would make it more clear that in any transaction between one doctor and another it would be quite legitimate for the price to cover adaptations in the premises which would be of no value to a purchaser other than a doctor. Any adaptations to the inside of a house were to be allowed to be paid for.

The amendment was agreed to, but an amendment by Col Elliot to omit the provision authorizing the court to apportion the consideration was defeated by 26 to 15.

In subsection 5, dealing with services performed as an assistant to another medical practitioner for a remuneration substantially less than those services might reasonably have been expected to be worth and followed by a succession to the practice, Mr REID moved to amend the proviso that an offence should not be deemed to have been committed if it were shown that the remuneration of the assistant was not fixed in contemplation of his succeeding to the practice. Mr Reid moved to make this fixed by the second practitioner. He said he really did not understand what the Clause meant. He wanted to know what was the position if one practitioner had in mind a succession to the practice and the other had not. There might be a case of a new man who deliberately accepted too small a remuneration without there being any intention on the part of the older man of letting the new man buy the goodwill in this roundabout way. Medical men on the Committee would agree that that was a possible situation. On the other hand an older man might deliberately get a new man to come into the practice too cheaply intending later to offer it to him whereas the new man did not realize he was being made use of in this way.

Col ELLIOT suggested that an assistant might take a post at a small remuneration in a district where there was a rapid increase in the practice. It could then be said that this young man succeeded to the practice in consideration of a totally inadequate remuneration. The older practitioner might have thought that this development was not coming so quickly.

The LORD ADVOCATE said that under the subsection regard must be had to the situation at the time when the bargain was made. If the parties could show that the remuneration was fixed on its merits and not in respect of any question of goodwill there was no offence.

Mr HASTINGS said it was true that the subsection contained a serious danger of the professional man coming into collision with the courts but the professional man still had the right to plead that he did not understand and Mr Hastings thought he would be in a good position. The proposed amendment was rejected by 28 to 12.

In subsection 6, which ends with a proviso that it shall not apply to anything done in relation to the acquisition of premises for the purposes of a medical practice, Mr REID moved to insert after 'premises' the words 'or other property'. He said the proviso guarded against the possibility that the subsection as at present drafted would make it an offence for the incoming man to buy the house. But the new man might buy from the old practitioner other things than a house. He might buy surgery equipment of different types. Under the subsection if the incoming man gave a price for any of these movable articles and thereafter succeeded to the premises, then that payment would land him in jail because the transaction was deemed to be a sale of the goodwill.

The LORD ADVOCATE replied that the point made by Mr Reid was met in the closing lines of subsection 6 (b) 'unless it is shown that no part of the consideration was given in respect of the said goodwill or part thereof'. After further discussion Mr Reid's amendment was rejected by 25 to 12 and the Committee adjourned.

Sale of Medical Practices

When the Committee resumed on March 6 Mr J S C REID moved to amend Clause 34. In subsection 9 he asked the Committee to delete proposed from the provision that any medical practitioner or a personal representative of a practitioner might apply to the Scottish Medical Practices Committee for their opinion on whether a proposed transaction involved the sale of the goodwill or part of the goodwill which it was unlawful to sell under the section. Mr Reid said that this only allowed proposed transactions to be put before the Committee for their approval or otherwise. The purpose of his amendment was to give a certificate that the bargain was all right and that those who had entered into it would not be harassed by the complicated provisions in the earlier part of the Clause. If Mr Buchanan would undertake to put in during the Report Stage some time limit within which the Medical Practices Committee would give its decision, that would meet the case nearly as well as acceptance of his amendment. In the absence of such a concession he did not think it safe to assume that these decisions would be given promptly.

Mr BUCHANAN said he did not think that acceptance of a proposal to insist on decisions within three weeks would be an improvement. Time limits to answers from committees were not always good. He liked Mr Reid's other proposal even less. It would allow the doctor to carry out a transaction and leave the Committee to decide afterwards. He agreed with Mr Reid that practically 99% of the cases would be innocent.

Mr REID withdrew his amendment and moved to insert that the Medical Practices Committee should grant the certificate requested unless they found reason to believe that there was something wrong in the transaction. His form of words was intended to replace the words in the Bill if they are satisfied that the transaction or series of transactions does not involve the giving of valuable consideration. Mr Reid pointed out that under the words of the Clause the Committee would give a certificate only if satisfied that the negative had been proved. He said it was surely sufficient to direct the Committee to give a certificate unless they had reason to believe that something was wrong.

The LORD ADVOCATE said he could not accept this amendment.

Mr SCOLLAN asked whether the Lord Advocate and Mr Buchanan were prepared to reconsider the matter. He suggested that the Committee could at least insert unless they find reason to believe. He said that immediately the National Health Service came into operation there was bound to be a reshuffle of practices. Older men would say that they would retire because they could not be bothered any more about it.

Mr BUCHANAN said he did not propose to reconsider the matter. The closure was carried by 21 to 12 and the amendment was defeated by 22 to 12.

Mr REID moved to amend the passage in subsection 1 making a proviso that if it appeared to the court that the applicant had failed to disclose all the material circumstances the court might disregard the certificate. He proposed to insert the word wilfully. He said that as the Clause stood if the man omitted from his letter to the Committee something which he thought irrelevant then there was a risk that an innocent person might be prosecuted ten years afterwards even if there was no element of fraud.

Mr BUCHANAN said that the facts would have to be reported to the Procurator Fiscal. The Medical Practices Committee would not report cases to the Scottish Office and cases would not come to the Lord Advocate directly. The proposed amendment was defeated by 22 to 16.

Black Marketing in Goodwill

On the motion that Clause 34 as amended stand part of the Bill Col ELLIOT said the complexities of the discussion on this Clause showed the difficulty into which the Government had put itself. It had got itself into almost inextricable legal and administrative tangles. Four pages of type were required to set down the considerations which should be brought in to enforce this decision, and these pages might not comprise all the considerations which would be brought in. The whole Committee agreed that it was creating a new kind of offence hitherto unknown in Scottish medical practice—what the Lord Advocate had described as black marketing in goodwill. That phrase showed to what depths Parliament was sinking in this particular Bill.

Mr SCOLLAN said there were parts of the Clause which the Government might well reconsider before bringing the Bill back to the House of Commons. He had a son who was a doctor. Nothing in the Bill would prevent him buying a house, paying a black market price for it, and handing it over to his son.

Mr BUCHANAN said objections came from some members on his side who had a fundamental objection to the sale of practices. He asked the Committee to remember that the medical profession were getting £66 million of public money and the Government had a right to see that the profession did not get that money twice over. He admitted that the practices against which the Clause was aimed were the most difficult things in the world to stop.

Major LLOYD said the Clause was based on an unsound principle which deprived British people of the normal right of freedom in property. If a doctor had bought a house why should he not sell it if he so desired?

The Clause was approved as amended by 24 to 16. Discussion then opened on Clause 35 just before the Committee adjourned.

EPIDEMIOLOGICAL NOTES**Smallpox at Grimsby and Stepney**

In the outbreak of smallpox at Grimsby which we recorded last week (p. 320) there had been 15 cases with 6 deaths, all in the direct line of contact, by March 10. The situation at Grimsby is now believed to be fairly satisfactory.

One case of smallpox was diagnosed in Stepney on March 9. The patient was a member of the staff of a seamen's hospital. He fell sick on Monday March 3 and was admitted to the Mile End Hospital during the week. A diagnosis of smallpox was made on Sunday, March 9, and he was transferred to the hospital at Clandon, Surrey.

Acute Gastro enteritis in Ammanford

There were recently about 300 cases of acute gastro enteritis in the Ammanford area of Carmarthenshire. The first cases appeared on Nov 15 1946, and varied in severity. Some had mild diarrhoea others severe vomiting and diarrhoea with blood in the stools. Profuse growths of organisms of the *Salmonella* group were obtained from several specimens of faeces. On further investigation it was found that in nearly every case prepared meats, especially pressed beef and sausages, had been eaten.

The staff at the local butcher's shop consisted of the butcher, his wife his son and two female assistants. One of the assistants was taken ill with gastro enteritis two days before the outbreak began and was away from the shop from the first day of her illness. Specimens of faeces were collected from the rest of the staff. Three were negative but that of the remaining female assistant produced a growth of *Salmonella* organisms. She was suspended from work immediately as a probable carrier and remained off work until three consecutive negative specimens of faeces had been obtained.

Specimens of gelatin used in the preparation of the meats were taken but were all negative. It seemed that the cause must be a foodstuff which had been eaten by both the female assistants producing symptoms of gastro enteritis in one but not in the other. The latter becoming a carrier. After much questioning it was found that three days before the start of the outbreak both assistants had eaten some bananas.

An interesting point was that the father of the suspected carrier was taken ill with gastro enteritis although he had not eaten any of the meats. His food however had been prepared by his daughter. The outbreak cleared up quickly once the suspected carrier was suspended from work. There were no fatal cases.

Discussion of Tables

In *England and Wales* an increase was recorded in the notifications of whooping cough in both weeks, 122 and 263. A

fall in both weeks was reported for measles and acute pneumonia, the notifications being 1,493 and 444, respectively, fewer than in the previous fortnight.

Only small variations in the trend of scarlet fever occurred throughout the country. The incidence of pneumonia declined in all areas. The only notable changes in the local trends of whooping cough during the fortnight were increases in Yorkshire West Riding 100 and Middlesex 47.

Changes in the incidence of measles have been dominated by the experience of Lancashire with a decrease of 1,185 in the notifications during the fortnight. Other large decreases in the incidence of measles were in Yorkshire North Riding 204, Durham 203, Kent 150, Devonshire 140, and Nottinghamshire 104. The largest increases were Yorkshire West Riding 262, Surrey 125, and Berkshire 100.

The returns for dysentery during the week ending Feb 15 were the lowest for six years. During the week ending Feb 22 dysentery reappeared after an interval of a fortnight in Hertfordshire, St Albans R.D., and 29 persons were affected.

During the first eight weeks of this year 81,080 births have been registered in the great towns, which is 139% of the total registered in the same period last year. The stillbirth rate has fallen to 27 per 1,000 of the total births during this year compared with 31 per 1,000 during the same period of 1946.

In *Scotland* the chief feature of the returns for the past fortnight was an increase in dysentery of 32 in the week ending Feb 22. This rise was due to an outbreak in Banff County involving 38 persons.

In *Eire* a fall in the incidence of measles and a rise in the notifications of whooping cough were the only changes in trend during the fortnight. Cases of measles fell from 66 to 33, but cases of whooping cough rose from 66 to 108, of which 100 were recorded in Dublin C.B.

In *Northern Ireland* the epidemic of measles in Belfast C.B. continued to decline and 287 cases were notified during the week ending Feb 22 as compared with 739 a fortnight earlier.

Tuberculosis Mortality

The death rate from respiratory tuberculosis rose during the first year of the war from 522 per million in 1939 to 588 and 602 in 1940 and 1941. In 1942 the death rate fell to 542. The mortality for the first half of 1946 compared with pre-war experience is shown in the following table.

Death Rates from Respiratory Tuberculosis per 1,000,000

Ages	Males			Females		
	Average of 1931-35	1939	1st half of 1946	Average of 1931-35	1939	1st half of 1946
0+	85	54	71	74	38	64
5-	42	15	31	43	20	26
10-	64	31	26	143	86	78
15-	489	368	236	842	601	507
20-	967	682	517	1,144	955	859
25-	966	723	658	914	707	658
35-	1,135	859	739	644	469	410
45-	1,369	1,158	1,101	474	352	270
55-	1,175	1,171	1,227	392	300	265
65+	610	559	712	265	209	177
Crude death rate	768	638	613	543	410	355

The death rate for both sexes at ages under 10 still remains above the immediate pre-war level. The only other age group with an excess is that of males aged 55 and over. The only age group with a rate higher than in 1931-5 is that of males aged 65 and over.

The death rate for tuberculous meningitis fell in 1946 but at ages 5-14 the mortality is still in excess of the 1939 level.

**Tuberculosis of Meninges and Nervous System
(Death rate per 1,000,000)**

Ages	Boys				Girls			
	1939	January-June			1939	January-June		
		1944	1945	1946		1944	1945	1946
0+	284	313	310	269	252	257	262	210
5-	97	118	130	110	77	105	120	104
14-	52	70	68	89	66	86	81	81

Week Ending March 1

The notifications of infectious diseases during the week in *England and Wales* included scarlet fever 1,167, whooping cough 2,290, diphtheria 186, measles 13,337, acute pneumonia 981, cerebrospinal fever 74, dysentery 92, acute poliomyelitis 8, smallpox 5, typhoid 5. Deaths from influenza in the 126 great towns numbered 121.

INFECTIOUS DISEASES AND VITAL STATISTICS

No 7

No 8

We print below, a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Feb 15

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland
Figures of Births and Deaths and of Deaths recorded under each infectious disease are for (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland
A dash — denotes no cases a blank space denotes disease not notifiable or no return available

Medical News

We announce with regret the death of Prof Bryan Austin McSwiney, FRS, Dean of St Thomas's Hospital and Professor of Physiology in the Sherrington School of Physiology

A conference arranged by the Electron Microscope Group of the Institute of Physics and the Royal Microscopical Society will be held at B M A House, Tavistock Square, W C 1, on Thursday and Friday, March 20 and 21, at 7.30 p.m. each day, when the following public lectures will be delivered: March 20 Mr J. Smiles, "Survey of the Inter-relationship of Microscopical Techniques"; March 21, Prof W. T. Astbury, FRS, "The Electron Microscope"

A meeting of the London Jewish Hospital Medical Society will be held at Woburn House, Upper Woburn Place, London, W C, on Thursday, March 20, at 8.30 p.m., when an address will be delivered by Miss Muriel Landau, FRCS, on "Recent Advances in Gynaecology"

The following radiological meetings will be held in London this month: Friday, March 21, 2.30 p.m., at Royal College of Surgeons of England (Lincoln's Inn Fields, W C), Diagnostic Section of Faculty of Radiologists: Dr S. Cochrane Shanks, "Hiatus Hernia"; Friday, March 21, 8 p.m., Section of Radiology of Royal Society of Medicine, 1, Wimpole Street, W: Dr J. F. Brailsford, "Some Experiences with Bone Tumours"; Friday and Saturday, March 21 and 22, meetings of British Institute of Radiology at French Institute, Queensbury Place, S W: March 21, 5 p.m., Dr F. Baclesse, "Cancer of the Larynx"; March 22, 10.15 a.m., presidential address by Prof D. W. Smithers, 11.20 a.m., papers on treatment of carcinoma of the cervix: 2 p.m., demonstrations at Royal Cancer Hospital

The seventh annual general meeting of the Colour Group of the Physical Society will be held at the Royal Photographic Society's rooms (16, Prince's Gate, South Kensington, S W) on Wednesday, March 26, at 3.15 p.m. A science meeting of the Group will follow at 3.30 p.m., when a paper by Mr M. E. Clarkson and Drs O. L. Davies and T. Vickerstaff on "A Statistical Investigation of Some Aspects of Colour Harmony" will be read

The seventh Clarke Hall Lecture on "Mental Health and the Offender" will be delivered by Dr J. R. Rees in the New Hall of Lincoln's Inn, W C, on Wednesday, March 26, at 4.30 p.m.

A meeting of the Middlesex County Medical Society will be held at Glaxo Laboratories, Greenford Road, Greenford, on Thursday, March 27, at 2.30 p.m., when Dr H. M. Walker will speak on "Laboratory Investigation of Drugs" and Dr E. Lester Smith on "Biological Substances (Liver Extract and Folic Acid)"

A meeting of the Scottish Group of the Association of Industrial Medical Officers will be held at the Western Infirmary, Glasgow, on Friday, March 28, at 2.30 p.m., when Mr Roland Barnes will speak on "Back Injuries in Industry". A clinical demonstration will follow.

The annual clinical meeting of Guy's Hospital Dental School will be held in the dental department of the hospital on Saturday, March 29. Morning and afternoon sessions will be held and demonstrations of modern dental procedures given by members of the staff: cases of clinical interest will be shown.

The Ministry of Fuel and Power will exhibit structural insulation, domestic heat services, and district heating, at the Scottish Fuel Efficiency Exhibition, to be held at the Kelvin Hall, Glasgow, from March 19 to April 5.

The International Committee of the Red Cross is holding a conference at Geneva in March to study the question of reviving the Geneva and The Hague Conventions. The Comité International de Médecine et de Pharmacie Militaires has prepared a report for their consideration.

A reunion dinner for ex CMF-MEF physicians, including neurologists, dermatologists, psychiatrists, and radiologists, will be held at Grosvenor House, Park Lane, London, W 1, on Saturday, April 26, at 7 p.m. for 7.30 p.m. The cost of the dinner will be 25s exclusive of wines. Those interested are asked to communicate before March 31 with either Dr W. MacLeod, 3, Drumsheugh Gardens, Edinburgh, or Dr A. Willcox, 66, Harley Street, London, W 1. As numbers have to be limited owing to catering difficulties, early applications are invited.

The Lord President of the Council has appointed the following to serve on the Advisory Council on Scientific Policy: Sir Henry Tizard, chairman, Sir Edward Appleton, Sir Alan Barlow, Sir Howard Florey, Sir John Fryer, Sir Claude Gibb, Sir Edward Mellanby, Sir Edward Salisbury, Sir Ewart Smith, Sir Reginald Stradling, Prof A. R. Todd, Dr A. E. Trueman, Prof S. Zuckerman.

The Medical Society of London held its Anniversary Dinner on March 6, Sir Philip Manson-Bahr, the President, being in the chair. The toast of the Society was proposed by Lord Oaksey, who as Lord Justice Lawrence was the British President of the International Tribunal at Nuremberg. Lord Oaksey gave an interesting talk on the implications of the Nuremberg trial, pointing out that the existence of international law carried with it a limitation of national sovereignty. The health of the visitors was proposed by Mr A. Dickson Wright and responded to by Lord Moran. The former observed that John Coakley Lettison was one of the last pair of seven sets of twins, and with his brother the only ones to survive. Lettison's father was a Quaker planter in the West Indies. John Coakley was born in 1744, was sent to England in 1750, founded the Medical Society of London in 1773, and died in 1815.

Three hundred doctors and medical students at the Johns Hopkins Hospital, Baltimore, watched on television screens as surgeons performed an operation. The experiment is regarded as a new and effective method of surgical education. Two television cameras were used, one mounted over the operating table itself and the other equipped with a telephoto lens, in the gallery of the operating theatre. The surgeon performing the operation gave a running commentary through a microphone mounted above the table. Television receivers were placed in other parts of the hospital and the students could watch the operation closely "without crowding round the patient." Dr Edwin Crosby, the director of the hospital, commented: "Television has brought the operative field within the critical sight of large numbers of doctors and students and will permit them to witness many operations."

We have received from the Melbourne Permanent Postgraduate Committee a copy of the syllabus of medical postgraduate facilities for 1947, which include continuous and intensive refresher courses, late afternoon courses, a course for dermatologists, country courses for higher degrees and diplomas and by overseas lecturers, film afternoons, supernumerary residencies and individual postgraduate study. The programme opened in February and each month until November a number of the above mentioned courses will be held. Full particulars may be obtained from the director of the committee, Dr F. Kingsley Norris, CBE, DSO, c/o Royal Australasian College of Surgeons, Spring Street, Melbourne, C 1, Australia.

Mr E. D. Macgregor, CB, Director of Establishments in the Ministry of Health since May, 1939, is retiring from the public service on March 31. Mr E. M. T. Firth, Assistant Secretary of the Establishments Division, has been promoted to be an Under Secretary, and the Minister, with the approval of the Prime Minister, has appointed him to succeed Mr Macgregor as Director. Mr S. J. Wilkinson has been promoted to be an Under Secretary in the Ministry.

Dr Arthur Massey, CBE, medical officer of health to the City of Coventry since 1930, has been appointed Chief Medical Officer to the Ministry of National Insurance at a salary of £2,250 per annum. Dr Massey, who will take up his appointment shortly, is to advise the Minister on medical matters in connexion with the administration of the National Insurance Act and the Industrial Injuries Act.

We have received recently the *Handbook* for 1946 of the National Children's Adoption Association. It includes a report of the Executive Committee from April, 1944, to March, 1946, and can be obtained for 1s on application to the Association at 71, Knightsbridge, London, S W 1.

A. O. Davy, FRACS, L. F. Dods, MD, FRACP, C. C. Finlay, MB, ChM, Prof B. T. Mayes, FRACS, FRCOG and Group Capt H. R. G. Poate, FRCS, FRACS, RAAF have been appointed MVO (Fourth Class).

Dr Donald Paterson has recently been made a Corresponding Member of the Société de Pédiatrie de France and an Honorary Fellow of the American Academy of Pediatrics.

Prof John A. Ryle received the honorary Doctorate of Science from McGill University, Montreal, at Oxford, on March 11.

Mr R. M. De Mowbray, FRCS, of Lymington, Hants, who died on Sept. 24, 1945, left £55,894. Dr J. A. Pringle of Canterbury, who died on Feb. 12, 1946, left £36,631. Lieut-Col A. Whitmore, MD, IMS (ret), of Medleying, Cambs, who died on June 26, 1946, left £31,376. Dr A. F. Voelcker, FRCP, of Marhamchurch, Cornwall, who died on June 9, 1946, aged 84 years, left £16,559. Col Hugh Murray Morton, CM, CBE, DSO, late RAMC, of Berwick on Tweed, who died on Aug. 7, 1946, aged 73, left £23,036. Dr William Evans Thomas, JP, of Rhondda Glamorganshire, who died on Jan. 20, 1946, aged 82, left £38,19. Dr Benjamin Rigby Johnston, of Westmorland, who died on March 17, 1946, aged 84, left £15,919. Dr Herbert Harland Ra of Whitby, who died on Aug. 5, 1946, aged 68, left £9,802. Dr Herbert Charles Meacock, who died on Feb. 28, 1946, left £83,921. Dr Elizabeth Stanton, MRCS, LRCP, who died on Feb. 1, 1946, left £37,972 gross, with net personality £37,819.

STILBOESTROL and related SYNTHETIC OESTROGENS

Every medical practitioner should send for a copy of 'Stilboestrol and Related Synthetic Oestrogens'—a 32-page manual compiled by the scientific staff of Clinical Products Ltd.

This manual is designed to give quick, easy access to available data on these important substances and covers the significant works of leading investigators in the field of Stilboestrol research.

Menopax preparations—both the tablets and the anti pruritic cream—are in constant and ever-increasing production to meet demand. Free medical samples and a copy of this book will be gladly forwarded on application to—

for BASAL
INTRAVENOUS
or TOTAL
ANAESTHESIA

SOLUBLE THIOPENTONE
BOOTS is an intravenous anaesthetic of proved value. As a basal anaesthetic prior to general anaesthesia it has been used extensively and has given uniformly good results over a considerable period under widely varying conditions and dosage.

Soluble Thiopentone has been used successfully and is recommended as a total anaesthetic for short minor operations and also for long operations which do not demand considerable muscular relaxation.

SOLUBLE THIOPENTONE is a mixture of 100 parts by weight of the mono-sodium derivative of 5 ethyl 5 (2 methylbutyl) thiobarbituric acid and 6 parts by weight of anhydrous sodium carbonate as laid down in the B.P. Addendum VII. Available in Boxes of 6 and 25 ampoules of 0.5 gm and 1.0 gm.

for the sake of convenience we have decided to change the name of our increasingly popular gauze dressing from 'Optrex Tulle' to Optulle. This Tulle Gras dressing itself, however, has not been altered in any way. It remains exactly the same—a wide mesh gauze impregnated with Balsam of Peru in a greasy base—suitable for a wide variety of uses, particularly for raw surfaces including burns and septic wounds, and for plastic surgery cases.

Supplied in tins of 24 dressings, 4 ins square (approx)
Prices to the Medical Profession 4/- per tin or 45/- per dozen

The improved
tar preparation

E.S.T.P.

BRAND

(MARTINDALE)

Ether Soluble Tar Paste

Purified, decolorised, non staining,
aromatic, maximum Tar effect

FORMULA

Ether Soluble Tar Distillate	1.5%
Zinc Oxide	14.0%
Starch	12.0%

In a special emollient base

A smooth paste easily applied. The tar component retains the essential phenolic compounds unimpaired ensuring powerful antiseptic action. All indications for Tar Treatment are indications for 'ESTP' (Martindale) more especially infantile eczema, eczema generally, impetigo, complicating eczema, prurigo, pruritus, psoriasis, pityriasis, circinata, lichen planus. In 2 oz and 16 oz pots. Sample and literature on request.

and REGAIN

Elastoplast Technique was evolved with 'Elastoplast' Bandages and Dressings. The successful results described in medical and surgical publications were achieved with 'Elastoplast' Bandages and Dressings.

The combination of the particular adhesive spread with the remarkable stretch and regain properties of the woven fabric, together provide the precise degree of compression and grip shown by clinical use to be essential to the successful practice of the technique.

These properties, peculiar to 'Elastoplast', have produced a bandage used for many years with outstanding success by the Medical Profession throughout the world.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Penicillin in General Practice

Q—I should like advice on the uses of penicillin in general practice. An indication of the types likely to be most useful to the G.P. a few notes on storage and the recommended dosage for the more ordinary but none the less distressing conditions would be appreciated.

A—Penicillin powder as now supplied in sealed ampoules is so much more stable than earlier products that it can be stored at ordinary room temperature for any reasonable period. Solutions are better kept in a refrigerator unless used within a few days as are creams. The temperature in the open part of a domestic refrigerator—about 40° F. or 4.4° C.—is satisfactory.

Some minor conditions can be treated by the local application of penicillin impetigo by means of a cream and throat infections by oral tablets. Any infection not so superficially situated can usually be treated only parenterally—that is, by intramuscular injections. If this has to be done the fact that the lesion is small does not mean that the dose can be small in proportion. Whether a staphylococcus is producing osteomyelitis or merely a carbuncle of moderate size, the minimum concentration of penicillin required in the blood to check its further activity is the same. It is therefore useless to give penicillin intramuscularly in doses of less than, say, 20,000 units four hourly. If the interval between doses is longer than this the dose must be greatly increased. Hence this form of treatment is not usually worth while except in fairly severe or potentially dangerous septic conditions. There are now several books on the therapeutic use of penicillin, one of which the questioner is advised to consult for further details.

Treatment of Chronic Diverticulitis

Q—What is the best treatment for chronic diverticulitis in a patient of 72 who has been suffering on and off for the last ten years? There is a history of enteric and diarrhoea in the Boer War and dysentery followed by colitis after Gallipoli. The patient suffers frequent pain and discomfort especially at night. Some relief is obtained from colloidal aluminium silicate given during the day and codeine gr. 1 (2 (32 mg) at night. Is it advisable to go on with this? Would a course of sulphathalidine be worth trying?

A—This type of case often offers great therapeutic difficulties. It is advisable to continue with a low residue diet and mineral oil in some form, as these measures should diminish stasis and the risk of further infection. The predominance of pain at night suggests that intestinal flatulence is a factor and to diminish this it would be advisable to restrict bread and potatoes to a minimum, some help may be given by charcoal in finely divided form. Any superadded spasm would be reduced by belladonna or atropine. Unless there is abdominal tenderness it is unlikely that very active inflammatory change is in progress around the diverticula. If this is present it would be worth trying one of the sulphonamide drugs, preferably sulphadiazine or a similar compound. Sulphathalidine would be better avoided on account of its constipating effect. There is no harm in continuing with colloidal aluminium silicate and codeine for a time.

Teeth grinding

Q—What is the cause of teeth-grinding of sudden onset during sleep? What treatment is advised?

A—Teeth grinding during sleep is evidence of some degree of tension in the child and is in the same category as over-activity, restlessness, nail biting, etc. during the day and restlessness or disturbed sleep at night. It may be provoked by physical discomfort associated with skin irritation, enlarged adenoids, etc., and the traditional connexion with intestinal worms may

arise when they cause anal irritation. Most commonly however, the cause and treatment are to be sought in the daily life of the child. Such factors as an over-anxious mother, intra-familial stresses, undue restriction in the home or pressure at school should be explored. Spasmodic teeth-grinding has been quoted (Kanner *Child Psychiatry*) as being associated with neurological damage in juvenile paresis and it presumably may occur as a minor epileptic phenomenon. Such organic causes are extremely rare. The aetiology in adults is similar, but the stress is much more liable to be within the personality and less susceptible to modification of the outside situation.

Bee-stung Anaphylaxis

Q—A bee expert of 30 years experience when giving practical demonstrations makes a bee sting the back of his hand. He gets no local reactions or sensations whatever. Is he more liable to anaphylactic reaction than a beekeeper who is only occasionally stung?

A—There is evidence to suggest that frequently repeated stings produce a condition of immunity and that reactions are more likely to develop after occasional stings. It would seem, however, that some persons are more likely to develop reactions than others and this might well depend on whether or not they have an allergic personal or family history.

Treatment of Dipsomania

Q—What is the current authoritative medical opinion on the treatment of dipsomania by ingestion of large quantities of alcoholic drink followed by injection of apomorphine? It has been recommended for a patient of 49 and I am anxious to give it a trial.

A—An account of the treatment described is given in this *Journal* for March 18, 1944 at page 399, together with the references. It has been regularly used by Voegtlin in San Francisco, and by Reese in Madison Wis., and is certainly successful in willing subjects. The duration of cure differs, out of 1,042 patients treated only 40% were still cured 5 years later. The treatment can, however, be repeated at yearly intervals.

Thymol Turbidity Test

Q—What is the thymol turbidity test?

A—The thymol turbidity test is fully described by N. F. MacLagan (*Brit. J. exp. Path.* 1944, 25, 234) who devised it. It is an empirical test, derived from an accidental observation. The addition of thymol as a preservative to a solution used in the serum colloidal gold reaction was noticed to cause a turbidity or precipitate with sera from cases of parenchymatous liver disease. For details of the technique the original paper should be consulted. MacLagan gives its results in 248 cases of liver disease (positive in 91% of cases of infective hepatitis, 100% of hepatic cirrhosis, 47% of post-arsphenamine jaundice, 52% of Weil's disease and 7% of obstructive jaundice) and in 217 control patients of whom 21% gave positive results (cases of glandular fever, rheumatoid arthritis, heart failure, pernicious anaemia, etc.). A positive result is believed to indicate an increased serum gamma-globulin content.

Buccal Ulceration and Menstruation

Q—What are the aetiology and treatment of ulcers of the mouth which occur only near the time of menstruation? I have an edentulous patient aged 40 who has severe pain and signs of mild inflammation at one point on the lower jaw coinciding with a menstrual period. X-ray examination reveals no abnormality of the ramus.

A—Cyclical buccal ulceration occurring in relation to menstruation is a well recognized syndrome and there is often, but not always, a coincident ulceration of the vulva or lower vagina. The aetiology is unknown but there are many theories put forward to account for it. It has, without much evidence, been regarded as the result of an infection by a special bacillus, others look on it as a form of herpes. The view that it is an allergic manifestation is supported by the fact that there is sometimes a strong family history of other allergic diseases. The relation to menstruation and the fact that the ulceration clears up during pregnancy (but usually recurs afterwards) have given rise to several theories with an endocrine basis.

Various vitamin deficiencies and disturbances in the alimentary tract have also been blamed. It is possible that different mechanisms operate in different cases. Treatment is unsatisfactory. Protein-sensitivity tests should be carried out and any focus of sepsis in the mouth eradicated. Large doses of vitamin C might be tried. Chorionic gonadotrophin (500 i.u. intramuscularly twice weekly) appears to help in some cases, but may have to be continued indefinitely. See also replies to questions in the *Journal* for Dec 25, 1943 (p. 839), and June 15, 1946 (p. 940).

Green Teeth

Q—*I have a patient aged 2 years with green teeth. Has the Rh factor any bearing on this disease?*

A—The presence of true green teeth is a rare condition usually following icterus gravis, and has been noted in the permanent teeth of patients who have recovered from that disease in infancy. The Rh factor is, of course, connected with this disorder. The more common appellation of green teeth is given to teeth showing the characteristic green stain of chromogenic bacteria. This is often seen on the anterior teeth in children, and can usually be removed with mild abrasives.

Generalized Pruritus

Q—*An old woman of 75 is suffering from widespread pruritus. She was in good health though frail until a couple of years ago since when she has had burning pain at different times in the perivulval and perirectal region, the left side of the chest, left iliac fossa, the face and the forearms. The perirectal pain seems to be the worst. She has had no sugar in her urine. Any advice would be helpful.*

A—It is important to exclude carcinoma (especially of the stomach, rectum, or bowel), anaemia, or vitamin deficiency. In the absence of these the itching is likely to be psychogenic in origin, or may be due to arteriosclerosis, especially as it affects the central nervous system, or to vitamin B deficiency. Injections of liver and phenobarbitone in 1/2-gr (32-mg) doses may help. Locally Grenz-ray therapy, if available, should be applied, otherwise the following should be prescribed:

R	Acid carbol	mx (0.6 ml)
	Calamin	gr xl (2.6 g)
	Lanolin	gr xxx (2 g)
	Ol. oliv	℥ss (15 g)
	Aq. calcs	ad 3j (30 g)

Fiat cremor

Cocaine and allied preparations should never be employed.

Sweating Feet

Q—*A boy of 11 suffers from excessive sweating of his feet. There is the usual strong smell from his socks and shoes, and the boy is very conscious of the condition with a dread of elaborate treatment lest the other boys know. What can I do for him?*

A—This is emotional sweating, and the boy should take phenobarbitone gr 1/4 (16 mg) each night for three, six, or twelve months as may prove necessary. He should wash the feet every night, have clean socks daily, and use the following foot powder as a daily routine before putting them on:

R	Sod. hexametaphosph	5%
	Acid. salicyl	2%
	Zinc oxid	} aa ad 100%
	Talc	
	Acid. bor	

Fiat pulv

Congenital Syphilis

Q—*A woman whose husband has contracted syphilis has become pregnant by him. She herself has not contracted the disease and her Wassermann remains negative. Is there any chance of the baby being syphilitic?*

A—If the wife has not contracted syphilis she cannot give birth to a syphilitic child. *Treponema pallidum* does not pass in a spermatozoon to the ovum. However, the possibility must be considered that she has contracted the disease but shows no sign of it; it would therefore be wise to keep her under careful observation with periodical blood tests right up to term.

Letters and Notes

Sodium Morrhuate Injections

Mr HAROLD DODD (London, W) writes: The reply (Feb. 8 p. 243) to "What is the explanation of the 'fainting feeling,' pain in the ankle, and severe headache after the above is, I suggest, only partial. It seems to me that the essential is that sodium morrhuate is a substance of variable chemical composition. Some preparations contain an element which, when injected for the sclerosis of varicose veins, causes reactions varying from the above faint feeling to sudden death. I have reported one of the latter after 3 ml. of 5%. The journals also from time to time have told of other fatalities and collapses. Many medical men will describe experiences of the above undesirable reactions. The crux of the matter is, therefore, that sodium morrhuate should be abandoned forthwith for varicose vein sclerosis. It is dangerous quite apart from the fact that it is an indifferent sclerosing agent. I think its use is criminal. Even after injections of 'ethamolin' (a somewhat similar but stable preparation) occasional unpleasant reactions have been described in the medical press. May I recommend an alternative sclerosing agent whose qualities are safe, self-sterilization, powerful sclerosing action, a but slightly painful chemical thrombo-phlebitis, and no irritation when inadvertently injected outside veins. I have not seen an injection ulcer from it. Autoclaved gelatin 1%, glucose 25%, glycerin 30%, phenol 2% in distilled water. It is called P3G fluid. Dose 1-5 ml. It has one disadvantage during very cold weather: requires slight warming because the gelatin tends to thicken. I have used this daily for three months in hospital and private work with excellent results. I was reintroduced to carbolic acid as a sclerosant by Mr. Riddoch, of Birmingham, who tells me that he has injected it in another formula for years on thousands of occasions with consistent safety.

Health Service in Ancient Egypt

Dr T. S. WILSON (London, S.W.11) writes: Diodorus Siculus (1.82) writes the following about the health services of ancient Egypt: "In expeditions and journeys from the country all [the sick] are taken care of without giving pay privately, for the physicians receive support from the community, and they provide their services according to a written law compiled by many famous physicians of ancient times. And if after following the laws from the sacred books they cannot save the patient, they are let go free from all complaint, but if they act contrary to what was written, they await condemnation to death, since the law maker thinks that few men would have knowledge better than the method of treatment observed for a long time and prescribed by the best specialists." The passage of several millenniums does not appear to have altered the opinion of the law-maker to any considerable extent. May one, however, assume that the Minister of Health has at least decided against the reapplication of the ancient Egyptian penal code?

Penicillin Lozenges

Dr G. J. GRAINGER (London, S.W.4) writes: Could not penicillin be prepared in the form of gelatin base gums or pastilles as opposed to the present day lozenges? I suggest this for the following reasons: (1) They would take longer to dissolve, and therefore the action of penicillin in the buccal cavity would be prolonged, (2) many patients complain of the "chalky flavour" of the lozenges, (3) in some patients this produces marked nausea, (4) there would be less tendency to crush and swallow a pastille, (5) a smaller dosage of penicillin would be required in the treatment of oropharyngeal affections.

Correction

In the article "The Place of Unilateral Renal Disease in Hypertension" by C. W. HARDWICK and A. W. BADENOCH, published in our issue of March 8, the word hyperplasia at the beginning of the last paragraph of column 1, p. 295, should be hypoplasia and the sentence read: "In renal hypoplasia there is an immature rudimentary kidney."

POISONING WITH A PREPARATION OF IRON, COPPER, AND MANGANESE

BY

GILBERT FORBES, M.D., B.Sc., F.R.F.P.S., F.R.C.S.E.d

Lecturer in Forensic Medicine at the University of Sheffield Police Surgeon to the City of Sheffield

Most iron salts are relatively inert, and modern therapeutic practice recommends their use in full doses. Certain iron preparations are, however, apt to cause dyspepsia and even one Blaud's pill may occasion abdominal discomfort in susceptible individuals. According to Goodman and Gilman (1943) iron salts 'used in the treatment of anaemias may cause gastric distress, colicky pain, and diarrhoea. These complaints are more prominent after ferric salts than after ferrous salts, and more common with the soluble than the insoluble preparations.' They consider that this is especially true of ferrous sulphate owing in part at least to the smaller doses used.

Cases of poisoning due to the ingestion of iron are extremely rare. Smith and Cook (1934) mention a case of a girl who swallowed 1 oz (28 g) of ferrous sulphate and recovered. Nearly all the cases of poisoning by iron preparations are due to the tincture of perchloride of iron, but a case of iron encephalopathy has been reported by Hurst (1931) following the oral administration of huge doses of iron and ammonium citrate. He states that no other example of remote symptoms due to iron (other than local gastro-intestinal effects) has been reported.

Some experimental work has been done on iron poisoning but for the most part the method of administration has been by injection. McGuigan (1926) quotes Kunkel to the effect that the fatal intravenous dose of iron for dogs is from 20 to 50 mg per kg of body weight. Meyer and Williams according to McGuigan (1926), found that 0.6 g of ferrous sulphate injected into the veins of a dog caused pronounced vomiting and diarrhoea, 8 g given orally proved fatal to a dog in 26 hours, and the necropsy showed ecchymosis of the stomach and intestines. McGuigan also reports the death of a man following the ingestion of 45 ml of tincture of iron.

Copper sulphate falls into the category of irritant metallic poisons. Acute poisoning with this substance is very rare and fatal cases are still more uncommon. Consequently the fatal dose of this salt is unknown, but Smith and Cook (1934) advance the suggestion that doses of 1½ oz (42 g) and upwards would act as powerful irritants on adults and that a much smaller quantity would suffice to destroy infants or children. Copper sulphate is a powerful emetic and may be used clinically for this purpose in doses of from 5 to 10 gr (0.32 to 0.65 g). If taken in larger quantities it causes acute gastro-enteritis. Because of its irritant properties if this salt is given as an emetic and fails to act the stomach must be promptly emptied by some other means (Douthwaite 1931). Retained copper is absorbed from the intestine and passes to the liver where it is stored. It is excreted partly in the bile and partly in the urine.

The irritant properties of copper sulphate are to some extent an asset. On ingestion vomiting occurs promptly and diarrhoea follows later. These processes aid in eliminating the poison from the system, so preventing absorption and reducing the risk of remote toxic effects on other organs. It has been observed (Smith and Cook 1934) that in non-fatal cases jaundice is sometimes a symptom, and this indicates that copper salts are apt to lead to liver damage. A considerable volume of experimental work has been done on this problem in the form of animal feeding experiments. Mallory, Parker, and Nye (1921) announced that it was possible to produce pigmentation and cirrhosis of the liver in rabbits and sheep by the oral administration of copper salts or of metallic copper in powdered form. Their results have been confirmed by Hall and Butt (1928), and denied by Flinn and Von Glahn (1929) and by Polson (1929), who claim that copper does not produce either pigmentation or cirrhosis, and that the pigmentation seen by Mallory and his co-workers is a natural phenomenon in the rabbit and is due to diet only. More recently Mallory and Parker (1931) have repeated their experiments and have found that copper given by injection in sufficient doses will kill a rabbit in from 24 hours to two to three weeks, and that necrosis and pigmentation of the liver cells can be demonstrated histologically. They assert that by special staining methods they have succeeded in demonstrating the copper in the liver cells. If the rabbits survive for a variable period, cirrhosis of the liver follows. They also describe the occurrence of necrosis of the tubular epithelium of the kidneys. Their results are supported by Hall and MacKay (1931), who found that 50% of their copper-fed rabbits developed cirrhosis of the liver, and that large quantities of copper were stored in this organ. Indirect support is also given by the finding of Gordon and Rabinowitch (1933) that in cirrhosis of the liver in man the copper content is increased. Thus there seems to be some evidence that copper salts can produce liver damage in addition to the gastro-intestinal irritation admitted by all toxicologists.

Manganese is generally regarded as being a relatively non-toxic element. A search of the literature has failed to reveal a case of acute manganese poisoning in man. There are however, reports of chronic poisoning of industrial origin where the symptoms are those of hepatolenticular degeneration. The neurological syndrome resembles in some respects that characteristic of Parkinson's disease (Goodman and Gilman, 1943). Von Oettingen (1935) reports that the lesions of the liver and central nervous system seen clinically can be produced in animals with toxic amounts of manganese, while Hurst and Hurst (1928) failed to detect any changes in the brain even in

the presence of gross damage to the liver. A single large dose of a manganese salt given subcutaneously will prove fatal in one to two days, while smaller doses repeated will produce cirrhotic changes in weeks or months, similar changes are found in rats which have had manganese chloride added to the diet (Findlay, 1924). Hurst and Hurst (1928) also produced acute and chronic changes after giving injections of manganese. It is fairly clear that both acute and chronic damage closely allied to acute yellow atrophy and cirrhosis, as seen in man, can be produced in animals experimentally.

It is questionable whether these experiments have proved the toxicity of manganese under ordinary conditions in man. According to Richards (1930) the bulk of the evidence seems to show that when ingested, even in fairly large amounts, manganese compounds have no toxic effects. He quotes the work of Reiman and Minot (1920) and of von Oettingen and Sollman to prove that feeding manganese ores to dogs and pigeons over a long period and in large amounts fails to produce any significant changes in the manganese content of the blood and tissues or any pathological symptoms. Richards fed manganese to pigs and found no toxic symptoms after the daily ingestion of 3.5 g of manganese citrate for nearly nine months.

Case 1

A healthy boy aged 3 years 3 months took a box of tablets off the kitchen table in his home at 12 noon on April 23, 1946. According to the mother's estimate the box contained about 50 tablets. At 12.30 p.m. the same day the box was found to be empty, and the child admitted having swallowed all the tablets. Each tablet contained ferrous sulphate exsicc 3 gr (0.2 g) copper sulphate 1/25 gr (2.6 mg) and manganese sulphate 1/25 gr. Shortly afterwards the boy vomited and a few tablets were returned. During the afternoon of that day the child slept fitfully was thirsty and appeared to be very weak. At 6 p.m. he vomited again, and the vomitus was clear fluid only. He had a fairly comfortable night, and next morning his general condition had improved. On the following day he showed no symptoms likely to cause alarm till 10 a.m., when his skin became yellow, his pupils dilated, and he was very restless. The child's condition steadily deteriorated till 5.30 p.m. on April 25, when he died—53 hours after taking the tablets. Medical advice was sought by the boy's mother immediately she discovered what he had done, but no treatment was considered necessary in view of the fact that he had vomited. Actually he was not seen by a doctor till 48 hours afterwards and he had no treatment during the illness.

Post-mortem Examination.—The only significant external findings were a suggestion of jaundice in the sclerotics and some abdominal distension. The stomach contained 3 oz (75 g) of dark coffee ground material and the mucous membrane along the lesser curvature was brown and necrotic. The remainder of the mucosa was rather oedematous but not acutely inflamed. The anterior wall of the stomach was stained blue and the subperitoneal vessels were injected. The small bowel was filled with black semi-solid material which had stained the rather oedematous mucous membrane and there was vascular engorgement here also. The large bowel was healthy, but contained hard black masses of constipated faeces. The liver looked about normal in size weighed 510 g, was not unduly flabby and there was no pronounced wrinkling of the capsule. Both on the surface and on section this organ was in part bright yellow and in part reddish purple. The distribution of these areas was irregular and the normal liver markings had disappeared. The spleen was slightly enlarged and there was a very small quantity of blood stained fluid in the peritoneal cavity. The kidneys were in a state of advanced cloudy swelling and in the pelvis of each there was a small quantity of bright-yellow crystalline material. The bladder contained 1 1/2 oz (14 ml) of cloudy urine which was not grossly bile-stained. The only abnormalities noted in the respiratory system were a few haemorrhages each about 1/4 in (0.6 cm) in diameter at the lung roots and some thick mucus in the bronchi.

The heart muscle was pale and there were two small sub-endocardial haemorrhages on the posterior wall of the left ventricle. Further haemorrhages, similar to those seen on the lungs, were noted at the lower pole of the thymus and along the descending thoracic aorta. All the other organs were normal.

Histology.—The liver showed degenerative changes ranging from cloudy swelling to complete necrosis. Some of the liver lobules had entirely disappeared while in others the central cells still remained. Where the liver cells had vanished the capillaries were widely dilated and there were extensive areas of haemorrhage. General polymorph infiltration was in evidence and deposits of granular pigment were scattered about. There was necrosis of the gastric mucosa to varying depths. Throughout the stomach wall the vessels were intensely engorged and there were haemorrhages between the muscle layers. The submucous layer was infiltrated with polymorphs and in places there were minute abscesses. The tubules of the kidneys and the heart muscle showed cloudy swelling. The lungs were acutely congested and there was some oedema. Desquamated epithelium and red cells were present in the bronchi.

Chemical Analysis.—The liver and the bowel and its contents were wet ashed with nitric and sulphuric acids. The copper in the residue was determined polarographically, using a Tinsley recording polarograph, with the following results: liver 11.2 mg, bowel 5 mg. The manganese was determined by converting it to permanganate ion and measuring the absorption in a Hilger Spekker absorptiometer. The following results were obtained: liver, 4.2 mg; bowel 8 mg.

Case 2

At 7.15 p.m. on Sept 9, 1946, a 1 year-old boy swallowed a quantity of the same proprietary preparation as in Case 1. It is estimated that he took between 30 and 35 tablets. The mother at once gave him salt and water and when this failed to produce emesis she inserted her fingers into his throat and he vomited undigested food and a number of the tablets. Shortly afterwards the boy returned some brown material and within an hour fresh and clotted blood. The child was admitted to hospital 90 minutes after taking the tablets.

On admission he was pale, collapsed, and shocked with laboured noisy, moist and bubbly breathing. The pulse was thin and rapid, the rate being 170 a minute. There were dark brown stains on his mouth resembling dried altered blood. The percussion note of his chest was unimpaired and moist breath sounds were heard at all areas. All other systems appeared to be normal. On admission to the ward the child started retching and when held up by his feet he vomited about 1 oz (28 ml) of fresh bright red blood mixed with mucus. Immediate treatment was given to counteract the shock, warmth being applied externally. Gastric lavage was considered to be contraindicated and bland fluids were given in the shape of milk and iced water. His general condition improved and after a minimum (0.06 ml) of nepenthe at 10.15 p.m. he went to sleep. Four hours after admission the child again collapsed and appeared in extremis. The only positive findings were moist sounds in the chest and indications that the bronchial tree was full of fluid—presumably aspirated vomit. Intranasal oxygen was given, with slight improvement. The tablets in question were found to be radio opaque, and the neck, chest and abdomen were radiographed to determine whether any tablets could be seen in the stomach, bowel or respiratory passages. None was observed. Atropine 1/150 gr (0.43 mg) was given at 4.5 a.m. on Sept 10 and the child seemed slightly improved, but during the forenoon his temperature rose to 103 F (39.4 C). On the ground that an aspiration pneumonia was developing, a course of penicillin was started at 12 noon with the result that the temperature began to fall. During the day there was one bowel action, the stool being very dark brown and offensive. At 6 p.m. the child again collapsed and vomited a small quantity of reddish brown fluid. He was placed in an oxygen tent but he died at 1.30 a.m. on Sept 11—that is about 30 hours after taking the tablets.

Post-mortem Examination.—This was carried out 34 hours after death. There was no jaundice. The only positive finding externally was the presence of a blotchy rash on the abdominal wall. The trachea and bronchi were filled with thick greenish

and which, from its colour, obviously contained some of the pigmented coating of the tablets. Both lungs were congested, and in them there were areas of collapse and a few scattered small haemorrhages. There were a few areas of pneumonic consolidation in the lower lobe of the right lung. The stomach was empty. Under the peritoneum covering it some haemorrhages could be seen. The lining of the stomach was brown due to necrosis of the mucous membrane. The small bowel was normal, apart from an occasional area where the vessels were engorged. The large bowel was healthy and the contents of the bowel were stained black. The liver weighed 354 g and its capsule was smooth. The liver tissue was yellow, but there were no haemorrhagic areas. Cloudy swelling of the kidneys was present. The urine contained no bile and no urobilinogen or tyrosine crystals. The other organs were free from abnormality.

Histology—The liver showed cloudy swelling and some fatty degeneration but no necrosis. The gastric mucosa was necrotic to various depths and much of the necrotic lining had been shed. The whole wall was intensely congested and there were extensive areas of haemorrhage in all its layers. In the submucous layer accumulations of polymorphs could be seen. The sections of the lung showed a typical bronchopneumonia. Cloudy swelling of the pancreas and kidneys was noted.

Chemical Analysis—The liver and the bowel and its contents were analysed by the same method as was used in Case 1 with the following results: copper in liver, 2.88 mg; in bowel, 58 mg; manganese in liver 1.375 mg; in bowel, 3.56 mg.

Comment on Analysis

Quite a number of estimations of the normal copper content of the liver have been made and a few of those published have been summarized in Table I. Many of the

TABLE I—Normal Copper Content of Liver

Authority	Age	Copper per kg. of Liver	
		Fresh	Dry
Sheldon and Ramage (1931)	Foetus	mg (37.5)	mg 150

figures are given in terms of milligrams or copper per kilogram of dried tissue. The human liver contains approximately 75% of water (Gordon and Rabinowitch, 1933) and on this basis the figures quoted for dry tissue have been converted to milligrams of copper per kilogram of fresh liver. These figures are shown in parenthesis in Table I. It is at once apparent that there is a considerable variability in the results. This is due to two factors: first, the series of estimations was in most cases too short to strike a reliable average, as in any biological variable there is considerable deviation on either side of the mean; and secondly, the copper content of the foetal and infant liver is considerably in excess of that of the adult (Sheldon and Ramage 1931). From the figures quoted the average for infants up to 2 years is 40.4 mg per kg. of fresh liver, for children from 2 to 14 years 11.8 mg per kg., and for adults 7.2 mg per kg.

In Table II some estimations of the manganese content of the liver are quoted. It seems that this element is present in fairly constant amounts, and that there is no storage in fat (Brückmann and Zondek, 1939). The average content per kilogram of fresh liver is 1.8 mg.

TABLE II—Normal Manganese Content of Liver

Authority	Manganese per kg. of Liver	
	Fresh	Dry
Brückmann and Zondek (1939)	(1.75 mg)	7.0 mg
Cited by Brückmann and Zondek	(2.1 mg)	8.4 mg
Ramage <i>et al.</i> (1933)	1.75 mg	—
Richards (1930)	1.70 mg	—
Reiman and Minot (1920)	—	—

Table III shows the content of manganese and copper per kilogram of fresh liver in the two cases under consideration. There seems to be no parallel between the

TABLE III—Manganese and Copper Content of Liver in Cases 1 and 2

	Liver Weight	Copper per kg. of Liver	Manganese per kg. of Liver
Case 1	510 g	21.9 mg	8.2 mg
2	354 g	8.1 mg	3.9 mg

two. In Case 1 the liver contains about twice the amount of copper expected, and in Case 2 only a fifth of the normal average. In Case 1 the manganese in the liver is over four times the normal, while in Case 2 it is only twice. No reasonable conclusions regarding the passage of the absorbed copper to the liver can be drawn, because of the relatively small amounts ingested and the variability in the normal content in young children. In both instances the manganese content was substantially increased, which suggests that, as the basic figure is more constant, this element tends to pass to the liver.

Animal Experiments

In order to determine with certainty which of the ingredients of the preparation in question was responsible for the death of these two children, a number of animal feeding experiments were undertaken. Guinea-pigs and cats were used. In the first instance six pairs of guinea-pigs were treated with the tablets. One pair served as controls and were given 6 ml of water only. The remainder were dealt with in pairs with 5, 4, 3, 2, and 1 tablet respectively. Those given two tablets at 3 p.m. one day were all found dead next day at 9.30 a.m. The post-mortem findings were similar in all cases. The stomach showed a bluish-green patch on the greater curvature, and was distended with granular coffee-ground material heavily stained with fresh blood. The mucosa was brown and necrotic, and patches of it had been shed. Haemorrhages could be seen with the naked eye in the stomach wall. The upper part of the small bowel was injected and the contents were blood-stained. The large bowel and its contents were normal and the animals did not suffer from diarrhoea. The liver appeared normal and no abnormalities, apart from occasional haemorrhages on the lungs and pericardium, were noted elsewhere.

Histological examination of the stomach showed necrosis of the mucous membrane to varying depths, with detachment of the more superficial layers. The vessels were engorged and haemorrhages could be seen in the submucous and muscular layers. "Polymorph" infiltration of the submucosa was noted. No wholesale necrosis was seen in the sections of the liver, the commonest appearance being cloudy swelling. Some vacuolation of the cells was not uncommon, and this was more in evidence in those animals given the larger doses. Here the cytoplasm appeared granular and fragmentary, and sometimes the cell contained a nucleus isolated in a large vacuole surrounded by an intact cell membrane. These areas were irregularly scattered and did not bear any special relation to the portal canals. "Polymorph" accumulations in the liver sinuses were not uncommon, but the groups usually

amounted to no more than a half-dozen cells. No significant histological changes were observed in any of the other tissues.

The two controls and the two guinea-pigs given one tablet each remained apparently unaffected. One control and one of the other animals died later from bronchopneumonia. All four animals were dissected, and no abnormality was discovered in the gastro-intestinal tract.

Two cats were each given five tablets, and within a short time they became ill and vomited blood. One of the cats was killed 4½ hours later. The other cat survived but was ill for several days. It refused food, had no energy, and its coat was ragged. It had apparently completely recovered 18 days later when it was destroyed. The post-mortem examination of the first cat revealed naked-eye and microscopical changes in the stomach identical with those found in the guinea-pigs. All the other organs, including the liver, were normal. The second cat appeared to be perfectly healthy at necropsy and there was no histological abnormality of the stomach. Sections of the liver, however, showed changes similar to those seen in the guinea-pigs given the heavier dosage. Many areas looked healthy, while in others the cells were in various stages of degeneration up to complete necrosis. There were no large areas of necrosis, but rather small nests of cells here and there surrounded by healthy liver tissue. No regenerative processes were seen.

At this stage of the investigation it was apparent that when a certain dose of this preparation was exceeded it was relatively lethal to cats and guinea-pigs. To determine which ingredient was the noxious one, it was decided to administer them separately to a further batch of animals. To begin with, ferrous sulphate was used alone. This was given to four pairs of guinea-pigs in doses of 3 gr (0.2 g) each to the first pair, 6 gr (0.4 g) to the second, 9 gr (0.6 g) to the third, and 12 gr (0.8 g) to the fourth. One of the guinea-pigs given 3 gr died in 5 hours, the other survived, as did the pair given 6 gr, while those given 9 and 12 gr died overnight. The post-mortem findings were identical to those observed in the guinea-pigs previously treated with the proprietary tablets. The animal killed by 3 gr of ferrous sulphate weighed only 210 g while its mate weighed 445 g, the pair given 6 gr weighed 675 and 770 g. On considering those guinea-pigs killed by the smaller doses we find that, on an average, 1 gr (0.065 g) of ferrous sulphate per 64 g body weight will prove fatal (Table IV).

TABLE IV

Weight of Guinea pig	Dose of Ferrous Sulphate	Guinea pig Weight per Grain of Ferrous Sulphate
416 g	6 gr (0.4 g)	69 g
355 g	6 gr (0.4 g)	59 g
210 g	3 gr (0.2 g)	70 g
535 g	9 gr (0.6 g)	60 g
560 g	9 gr (0.6 g)	62 g
Mean		64

The fact that the ferrous sulphate alone had the same effect and produced pathological changes identical with those occasioned by the proprietary tablets suggests strongly that the iron salt is the noxious ingredient. It was therefore decided to give six fresh guinea-pigs manganese sulphate and copper sulphate together. The proprietary tablets contain 1/75 gr (0.87 mg) of these salts for each grain of ferrous sulphate, and it was found that about 1 gr of ferrous sulphate per 64 g body weight of guinea-pig would prove fatal. The first pair were given 1/75 gr of the manganese and copper salts per 64 g body weight, the second pair double that amount, and the third pair a

triple dose. This treatment had no effect of any sort on the guinea-pigs. It would appear, therefore, that the children and the experimental animals died from acute ferrous sulphate poisoning.

Conclusions

The proprietary preparation in question is widely used therapeutically and is generally regarded as being quite innocuous. This may be true in ordinary doses, but the two cases described and the results of the animal experiments clearly show that in very large doses this preparation may be highly dangerous. It is clear that these are cases of acute ferrous sulphate poisoning. This salt, in contact with the gastric juice, would be converted into the chloride which has a considerable irritant action. This accounts for the acute haemorrhagic gastritis found in the children and in the animals. The remarkable feature of Case 1 was the extreme liver damage found. We failed to produce comparable lesions in the experimental animals. Of course, in their case death occurred quickly, while the elder boy lived for 53 hours after taking the tablets. The allowed time for considerable toxic absorption from the damaged tissues of the stomach, and this alone may have been sufficient to produce the degree of liver destruction found. The younger boy lived for 30 hours, and in his case the liver damage was not nearly so great. He died from an aspiration pneumonia, and had he not contracted it he might well have recovered. The quantities of copper and manganese taken were too minute to have any toxic effect.

Summary

The toxicology of the salts of iron, copper, and manganese is briefly reviewed.

Two cases of fatal acute poisoning due to a proprietary preparation containing ferrous sulphate, manganese sulphate and copper sulphate are described.

The results of a chemical analysis of the liver and of the bowel and its contents are given in each case.

A short series of animal feeding experiments is described proving that the ferrous sulphate is the noxious ingredient in the preparation concerned.

I have pleasure in acknowledging the help I have received in this investigation. Mr R. Belcher and Mr G. W. C. Milner, of the Department of Fuel Technology of Sheffield University, very kindly performed the chemical analysis of the organs. Dr Beryl Smith, resident physician at the Children's Hospital, Sheffield, provided me with the clinical report on Case 2. Dr I. F. S. Mackenzie, Lecturer in Physiology at Sheffield University, undertook the feeding of the experimental animals. To these colleagues I am deeply indebted for their kindness and willing co-operation.

AN OUTBREAK OF DIPHTHERIA IN A HIGHLY IMMUNIZED COMMUNITY

BY

JAMES FANNING, MD, DPH

*Medical Officer of Health Borough of Malden and Coombe
and Urban District of Esher*

The outbreak described below is considered worthy of record because methods of immunization against diphtheria and of maintenance of the immunized state are still in the developmental stage, and anything which can throw light on the efficiency of our present methods is of value. One important point about which there still seems to be some disagreement is the value of the Schick test in the field as an indication of immunity. The amount of circulating antitoxin in the blood is considered to be a more accurate indication, but this investigation is impracticable for general application. The real measure of protection against diphtheria would probably be regarded as the rapidity and degree of response of the protective body mechanism to the toxins of the organism, it having already been sensitized by previous immunizing injections.

It is clear that immunization by generally accepted methods does not in every case necessarily protect from a sharp attack of diphtheria. It is also clear that diphtheria of at least moderate severity can occur in a Schick-negative person. In this event it could not be guaranteed that death would not occur if circumstances were unfavourable. The chief points brought out in the present outbreak are: (1) The possibility of an alarming outbreak of diphtheria in a highly immunized community (94% previously immunized, 80% Schick-negative). (2) The failure of previous immunization to protect against a severe attack in certain cases. (3) The occurrence of a high proportion of cases among Schick-negative reactors.

Description of Outbreak

The institution under consideration is a modern private day school for girls of all ages, run on up-to-date lines with good hygienic facilities. The buildings are airy, on two floors, and there is no overcrowding. The children come from a number of adjoining districts. The school has three divisions—senior, junior, and infants. Among the infants are a few small boys. The three divisions are mainly separate, but there is a small amount of mixing between the senior and junior schools in the main building. The infants' department is situated in a separate building which was formerly used for residential purposes, and, with the exception of a few children who stay for midday lunch, the infants do not mix with the other divisions. Dinners are not provided at the school, but about 20% of the children bring midday lunch and mix in one room during the lunch hour. The approximate numbers in the divisions are: seniors, 160, juniors, 70, infants, 100. The teaching staff numbers 15.

First Phase

The school was closed for half-term holiday from March 1 to 5 inclusive. On the 3rd information was received from an adjoining district that a child (Case 2) attending the senior school had been removed to hospital with diphtheria. Owing to the school being closed it was not possible to inspect the children in school, but a list of class contacts was obtained and the names were telephoned to the various districts on the same day. As a result of this information two more cases (Case 1 and Case 4) from the same class were discovered in an adjoining area. As soon as the school was reopened on March 6 all the children were inspected and swabs were taken from class contacts

and from any children showing the slightest suspicion of a pathological condition in the nose or throat. The number of children swabbed amounted to about 10% of those attending school, and all these results were negative. On this and ensuing days lists were prepared of children absent from school, and these were circulated to the medical officers of health of the districts where the children lived. This proved a very useful measure in the recognition of doubtful or missed cases.

The position on March 6 was that all the children attending school were well, and so far as was known they had not been in contact with a possible case for six days. In view of the fact that the great majority of the children (94%) gave a history of immunization, there appeared to be no urgent need for anything but continued observation at this stage.

In the meantime home inquiries brought to light several other pupils who had sickened during the holidays. The total number of cases belonging to this phase was eight (see Table I). Seven of these were senior girls and one was a junior girl. The infants' school was not affected. Seven of the cases became ill during the holiday week-end between Feb 27 and March 3. One of the cases (Case 1) developed what was apparently a mild tonsillitis on Feb 22 and this was followed by heavy nasal diphtheritic infection. This was the first case in point of time.

Second Phase

On Sunday, March 24, notice was received that a further case of diphtheria (Case 9) had occurred in one of the senior classes (Form IV) which had been involved in the previous outbreak. The date of onset in this case was given as March 22. This was 22 days after any of the previous cases had attended school. On March 25 a case (No. 10) was reported from another senior class (Form III) which had been previously affected. On the same day the whole school was inspected and Schick testing was carried out in the two classes involved. In the meantime arrangements were made to obtain the parents' consent for Schick testing and combined active and passive immunization where considered necessary for the whole school.

On March 26, with the exception of six objectors, the whole of the remaining school-children and staff were Schick-tested. Controls were used for the staff only. The intention was to give combined active and passive immunization to Schick-positives only, but as it was not considered justifiable to wait longer than 24 hours before adopting this treatment an early reading was taken, and this meant the inclusion of a considerable number of children with doubtful reactions among those who received immunization. Fifty-three per cent of the children had this treatment, which consisted of the injection of 0.3 ml of APT into the deltoid in the left arm and 500 units of diphtheria antitoxin similarly into the right arm. Six Schick-positive members of the staff were given 1 ml of TAF instead of APT. A Schick reading of the children after an interval of five days showed that actually only 20% were positive.

During the ensuing days throat and nasal swabs were taken from the whole school, including staff. On March 26 four more children went down, two of whom were in the junior school, but the infants' division was clear. The total number of carriers found without symptoms or signs was eight. Five children had positive throats only, two had a positive nose only, and the other had a positive nose and throat. A type report was available for seven out of the eight carriers, and all of these were group 1. Four carriers were in the senior division, one in the junior, and three in the infants (see Table III). Naturally, all of these

children were excluded from school. For various reasons general swabbing was not completed until April 6.

The school broke up for Easter on April 11 and four further cases were reported during the holidays. One case (No. 15) developed on April 9, 14 days after she had received 500 units of antitoxin and 0.3 ml of APT. Another case (No. 18) was taken ill on April 16, 21 days after similar treatment. The other two (Cases 16 and 17) were Schick-negative children who had not received any further injections, and they developed their illness on April 9 and 15 respectively. The number of clinical cases associated with the second phase of the outbreak now totalled 10 (see Table II).

During the week before May 2, the date on which the school was due to reopen, a further complete swabbing of

immunized, the degree of virulence must have been very high. The development of symptoms and membrane was in a number of cases extremely rapid. The virulence was such that a guinea-pig was killed in 24 hours. At some previous time all except two, or possibly three, of the 18 cases had received immunization which was probably adequate, and at least four were Schick-negative just before the onset of the illness. This probably accounts for the fact that there were no deaths. The state of immunization of the children was comparatively good, 94% having been immunized at some time previous to 1946. This was reflected in the Schick-negative rate, which amounted to 80%.

Analysis of the cases shows that three occurred among 23 children who had never been immunized (a case rate of

all the children and staff was carried out at the school by special appointment, the results were negative. At the same time a further 0.5 ml of APT was given to children who had been Schick-positive and a boosting dose of 0.5 ml was given to Schick-negatives. No further case occurred after April 16.

Discussion

A notable feature of the first phase was the explosive nature of the outbreak. Reviewing the cases in retrospect, it will be seen that one patient (Case 1) became ill about a week before the others, her illness having started on Feb. 22, the date she was last at school. It may be that the closing of the school for the half-term holiday period was instrumental in preventing further spread during this phase.

The reason why the infection remained quiescent for some three weeks and then flared up again is not clear. Where typing was carried out (12 cases and 7 carriers) the organism was of the gravis type. It is therefore a fair assumption that this type of organism was responsible for the whole occurrence. Judging by the severity of the illness in some of the children who had been previously

immunized, the degree of virulence must have been very high. The development of symptoms and membrane was in a number of cases extremely rapid. The virulence was such that a guinea-pig was killed in 24 hours. At some previous time all except two, or possibly three, of the 18 cases had received immunization which was probably adequate, and at least four were Schick-negative just before the onset of the illness. This probably accounts for the fact that there were no deaths. The state of immunization of the children was comparatively good, 94% having been immunized at some time previous to 1946. This was reflected in the Schick-negative rate, which amounted to 80%.

Analysis of the cases shows that three occurred among 23 children who had never been immunized (a case rate of 13%), while 15 occurred among 299 immunized children (a case rate of 5%). One case included in the first group (a case rate of 5%) received one injection more than 10 years before, and is not regarded as having been immunized. Dividing the immunized children into two groups—those immunized within five years and those before that period—it was found that the percentage of cases was approximately equal. It appeared, however, that with regard to clinical severity those patients more recently immunized had some advantage over the others. Bearing in mind that the numbers involved are small, the following table is given for what it is worth.

	Severe	Moderate	Mild
Cases immunized within five years	2 (20%)	3 (30%)	5 (50%)
Cases immunized longer than five years	2 (40%)	1 (20%)	2 (40%)
Cases not immunized	2 (66%)	1 (33%)	0

There was an anomaly in the infants' division. Taken by itself, although the immunization rate was 96% the Schick-negative rate was only 69%. It is rather striking that no cases occurred in this division, although there was evidence of a carrier condition in three cases. It is possible that there is a more rapid response of the protective mechanism to a secondary stimulus in the younger age groups.

The second phase of the outbreak was dealt with in general on the lines advocated by Fulton, Taylor, Wells, and Wilson (1941), with the exception that combined active and passive immunization was confined in the main to Schick-positive reactors. Four cases developed after this procedure, two were Schick-positives (Cases 15 and 18) who had received 500 units of antitoxin and 0.3 ml of APT 14 and 21 days, respectively, before the onset of their illness, and the other two (Cases 16 and 17) were Schick-negative children. In view of the fact that four cases went down in the 24 hours intervening between Schick testing and readmission, it is clear that it is inadvisable to wait even 24 hours for Schick-test results before carrying out immunizing measures in the face of virulent infection. Furthermore, four of the cases were Schick-negative reactors. The repeat swabbing and boosting doses to Schick-negatives before readmission after the Easter holidays were carried out as additional safety measures. A difference of opinion exists as to the value of general swabbing, and it is true that most of the carriers gave only one positive result, although a few were more persistent.

In this district, where the average incidence of diphtheria is low and the diphtheria carrier is almost non-existent, it has been the policy to swab close contacts and to take measures to restrict their movements when positive. In an episode such as this it would be difficult to ignore the possible danger to others from unknown carriers of virulent organisms and universal swabbing, with full recognition of its limitations, should be employed. It should, however, be completed in the shortest possible time so that all infected children, whether carriers or cases, may be excluded without delay.

It is clear from this experience that even a highly immunized community as judged by present-day standards is not entirely safe against a very virulent type of organism. It is also clear that immunization is of limited value unless it is maintained by boosting doses at regular intervals during the whole of school life. Opinions will differ as to how much of this work is necessary or practicable in order to reach the desired end. Parents do not take kindly to over-frequent injections for their children, and after infancy the frequency of sharp reactions with APT has a bad propaganda value for the whole scheme of immunization. Even TAF is not without its quota of discomfort. The Schick test is not reliable enough to justify the omission of immunizing injections in negative cases, but serves a useful purpose in measuring the conversion rate of various batches of antigen. In the present state of our knowledge it is suggested that the normal immunizing course in infancy should be followed by a boosting dose of selected antigen every three years irrespective of Schick-test readings. The antigen selected and the dose given will be a matter of individual choice.

Summary

An outbreak of diphtheria is described which occurred in a day school where 94% of the children had a history of previous immunization and 80% were Schick-negative.

The necessity for repeated doses of antigen during the whole of school life is emphasized. The interval suggested between doses is three years.

The limited value of the Schick test, as a measure of immunity is pointed out.

I should like to express my gratitude to Dr. Stone, of the E.M.S. Laboratory, Epsom, for her most valuable help in carrying out the bacteriological work, and to the medical officers of health of adjoining districts—Dr. Ellis, Dr. Iye, Dr. Johns, and Dr. MacIntyre—for their enthusiastic co-operation.

FAUCIAL DIPHTHERIA AMONG ARMY PERSONNEL IN BELGIUM, 1945

AN ANALYSIS OF 122 CASES

BY

J. H. BOLTON, M.D.

Lieut.-Col. R.A.M.C., Officer in Charge of a Medical Division at a General Hospital

AND

M. J. PIVAWER, M.B., Ch.B.

Major, R.A.M.C. Pathologist at a General Hospital

The purpose of this paper is to discuss certain aspects of the diagnosis and management of diphtheria in circumstances a little different from those usually obtaining in civil life. It was known before the invasion of Europe that diphtheria was prevalent in German-occupied Belgium and Holland, and it was recognized that when this part of the Continent was reached the disease might become a major medical problem. Consequently, compulsory lectures and demonstrations were arranged for medical officers of adjacent units. Prompt administration of serum was stressed and the admission to hospital of doubtful cases was encouraged. It followed that a very large number of patients who in normal circumstances would never have got beyond the stage of ambulant treatment were admitted to hospital for a brief period and had a thorough bacteriological investigation of their throats.

The Investigation

Bacteriology.—The absence of facilities for testing the virulence of organisms limited the scope of the investigation, and the bacteriological diagnosis has depended upon assessments from the point of view of morphology, cultural characteristics, and biochemical reactions of the organisms. The following bacteriological technique was employed. Preliminary throat swabs were plated on (1) tellurite plates (Hoyle's modification)—it is better to avoid human blood in this preparation as it is less inhibitory to organisms other than those of diphtheria, (2) blood-agar plates, 5% blood, (3) Loeffler slopes. A smear was stained with methylene blue and examined for Vincent's organisms. No attempt was made to diagnose diphtheria on the direct smears. The next day a combined smear was made from the Loeffler slope and the blood-agar plate and stained with Albert's stain. The blood-agar was also examined for haemolytic streptococci and the Hoyle plates were inspected for growth. If the slide was positive a diagnosis of morphological diphtheria was made and the result was immediately sent to the ward. The Loeffler slope which showed a morphological diphtheria bacillus was retained. If there was no growth on tellurite in 48 hours the Loeffler slope was subcultured to another tellurite plate. The following day the Hoyle plates were examined. Colonies were studied macroscopically and microscopically. All those showing a rod form were subcultured to a medium which was found to have an advantage over a Loeffler slope.

The medium consisted of 10% serum (animal sera were better than human), 100 ml of agar, 0.50 ml of neutral red as supplied for MacConkey's medium, and 1% saccharose. The last three were heated together until the agar was melted, and on cooling to 45.5°C the serum was added and it was then poured into Petri dishes. This medium was found to be of more value than subculturing back to Loeffler slopes, for the following reasons: (1) Colonies on this medium could be viewed and easily manipulated. (2) Frequently when using Loeffler slopes cocci were found as a contaminant on subculturing.

from Hoyle plates (3) Single colonies could be picked off with ease and put into saccharose Hiss serum water (4) With experience the saccharose and non-saccharose fermenters could be differentiated immediately (5) The morphology, altered by growth on tellurite, was immediately restored on the serum-saccharose medium The growth on the above medium was then subcultured to glucose and starch serum-water media Haemolysis was studied by subculturing on to 5% blood-agar plates

The diagnosis as to type was based on colonial appearances on tellurite plates, morphological appearance of organisms from a serum-sucrose medium, sugar reactions, presence or otherwise of haemolysis on blood agar, presence or absence of granularity in fluid media. Clearance swabs were plated direct on to tellurite and examined in 48 hours. If growth had occurred sugar reactions were determined.

Ward Procedure—Throat swabs were taken on admission and a preliminary laboratory diagnosis was obtainable by the following morning. This was confirmed later by subcultures and sugar reactions. Serum was given on clinical evidence, and where clinical and laboratory findings were at variance swabbing was repeated—often two or three times. Penicillin was being administered in the form of pastilles over a period of five days. It was not given until the diagnosis was certain, and it was considered desirable to wait five days after its last administration before starting the bacteriological investigation of the throat. As a result, clearance swabbing was not begun until the fifteenth to eighteenth day. Patients were swabbed—both nose and throat—on three consecutive days each week, until three negative swabs were obtained. Half of the cases clearing early had an additional swab or swabs beyond those necessary for clearance.

Material—The period covered was from Jan 1 to May 30, 1945, and records of 122 cases were available, 17 of which were not direct admissions. The latter are included, as they were observed for development of circulatory and neurological complications. In only one of these was the type of organism recorded, and they were excluded from investigations concerning duration of symptoms before admission, appearance of throat on admission, serum dosage, and, with the one exception, type of organism. Owing to the unexpected disbandment of the hospital a number of records were lost. Complete records of throat examinations were available only up to the end of April (Table I), but personal records of the actual cases of

TABLE I—Throat swabs January to April, 1945

Diphtheria	108
Vincent's angina	39
Haemolytic streptococci	985
Nil	33
Total	1,165

diphtheria were saved. The records of five cases were also lost, and these are incomplete as regards duration of symptoms, throat appearance, serum, and complications, but are available for type and, in all but one, throat clearance.

TABLE II

	Duration in Days							
	Less than 1	1-2	2-3	3-4	4-5	5-6	6-7	Total
No of cases	38	29	11	8	1	2	1	90

The result has been some differences in the total number of cases in the various analyses, but the manner of their omission excludes the possible introduction of bias.

Types of Diphtheria—Analysis of the first four months (Jan to April, 1945) showed the following types: *mitis* 49, *intermedius* 9, *gravis* 34, morphological 16, total 108.

The figures shown (Table II) regarding the *duration of symptoms* before admission speak well for the effectiveness of the lecture demonstrations.

Clinical Diagnosis

It became obvious that membrane formation as a basis for clinical diagnosis was relatively useless. Many cases were seen too early for the formation of true membrane, and five presented with no exudate at all, but developed it the following day. All of these five were seen on their first day. True membrane was found in only 27 cases, the remainder having exudate—follicular to confluent in type—readily wiped off by the swab (Table III).

TABLE III

	Exudate			True Membrane	Total
	None	Follicular	Confluent		
No. of cases	5	19	39	27	90
Average duration of symptoms on admission (days)	1	1.9	2.0	2.5	

Marked oedema of uvula, palate, and tonsillar regions was observed in 41 cases, and faucial oedema came to be considered of importance diagnostically—it being relatively rarely observed in the ordinary streptococcal throat. A very characteristic presenting type was the "two day quinsy", the appearance was due to marked oedema in the region of the tonsil—membrane or exudate being hidden behind the swollen mass. This was regarded as practically diagnostic of toxic diphtheria.

To summarize, the diagnostic criteria were as follows. Cases with membrane and the "two-day quinsy" cases were considered as definite diphtheria. Those showing confluent exudate were treated as diphtheria until proved otherwise by repeatedly negative swabs. Follicular exudate was viewed with suspicion, and the presence of oedema of the fauces was taken as strongly suggestive even in the absence of exudate.

Hypertoxic Cases—Seven cases showed marked toxæmia on admission. Four were of the "bullneck" variety, with oedema of the neck extending down over the clavicles, and one of these developed oedema of the glottis, requiring tracheotomy. All those observed long enough for its development—five—showed late neurological complications. None gave any evidence of serious cardiac involvement. The duration of symptoms before admission was 2-3 days in one case, 1-2 days in 4 cases, and less than 1 day in 2 cases.

Circulatory Complications—No serious cardiac complications were seen, and what changes were observed were very difficult to assess. Two cases developed extrasystoles for a short period in their third week. Four cases showed a pulse rate persistently below 50 per minute, but as they were all highly trained Commandos it was thought that this was a convalescence bradycardia. Four cases had pulse rates over 100 per minute while at rest, but at least two of them were very nervous individuals and one had been in hospital previously with a "nervous heart". Six cases showed tachycardia on leaving their beds for the first time. Seven cases had systolic blood pressures below 100—two on admission, the remainder at the end of the third week.

Neurological Complications

Out of a total of 101 cases observed long enough to develop neurological complications, 31 were reported as having done so. Five of these were doubtful, leaving 26 definite cases. The majority of these progressed no further than paralysis of the palate, which in many instances was very transient—lasting no longer than a week. Seven cases

had later involvement of the pharynx and limbs. Only two cases were recorded with accommodation paralysis, but, as it was never specifically inquired for, minor degrees were probably missed.

The average time of onset of paresis was palate 26, accommodation 34, pharynx 42, limbs 48 days. No respiratory or trunk paresis was observed, but cases with widespread involvement of limbs were evacuated and may have developed it subsequently. Of 32 cases showing faucial oedema 46.9% developed neurological complications as compared with 19.6% in 46 without oedema, out of a total of 78 cases whose records were complete in both respects. This difference gives a χ^2 of 5.39 and $0.05 > P > 0.02$, and indicates the value of faucial oedema is a diagnostic sign.

Toxaemia seems to be the main factor influencing the development of neurological complications (Tables IV-VI) in that in this series they appear to be relatively unaffected by duration of symptoms prior to admission, by early clearance of the throat, and by the administration of serum.

TABLE IV

Clinical Signs of Severity	No. of Cases	Proportion Complicated
Nil	46	19.6%
Faucial oedema	27	37.1%
Bullneck	5	100%

TABLE V

Day of Disease when Admitted	No. of Cases	Proportion Complicated
1st	29	27.6%
2nd	27	33.3%
3rd	10	30.0%
4th and over	9	33.3%

TABLE VI

Throat Clear by 3rd Week	No. of Cases	Proportion Complicated
Yes	41	35.5%
No	26	26.9%

Serum at first sight appears, if anything, to promote the development of neurological complications, but the fact that the more toxic cases received more serum probably accounts for the discrepancy (Table VII).

TABLE VII

Serum in Units	No. of Cases	Proportion Showing Signs of Toxaemia	Proportion Complicated
0-48 000	24	33%	25%
49-80 000	36	39%	25%
81 000 -	18	56%	50%

As would be expected, gravis infections showed a higher percentage of cases with neurological involvement. A comparison of gravis with all other types gave $\chi^2=7.42$ and $P<0.01$ (Table VIII).

TABLE VIII

Type	No. of Cases	Proportion Complicated
Gravis	27	48%
Inter-medius	8	13%
Mitis	40	20%
Morphological	10	10%

Treatment and Management

Serum—Serum was administered as soon as the clinical diagnosis was made and was repeated next day if no improvement had occurred. An attempt was made to give the full dosage as a single injection, the degree of toxaemia being assessed on the first examination (Table IX). The

intravenous route was used only with a serum dosage of 100,000 units or over. Hypertoxic cases received 100,000 units intravenously and 60,000 to 100,000 units intramuscularly. In addition they received penicillin intramuscularly—20,000 units 3-hourly up to a total dosage of at least 1,000,000 units. They also received penicillin

TABLE IX—Distribution of Serum Dosage

Dosage	No. of Cases
0-24 000	4
25 000-48 000	26
49 000-72 000	31
73 000-96 000	27
97 000-120 000	4
121 000-144 000	1
145 000-168 000	3
169 000-192 000	3
193 000-216 000	0
217 000-240 000	1
Total	100

pastilles by mouth. All patients were nursed flat for the first 21 days, or longer if complications intervened. Strict recumbency was not insisted on, they were allowed one pillow and were permitted to make themselves comfortable in bed.

Penicillin Pastilles—Penicillin pastilles were prepared by the method of Martín (1944) with 500 units per pastille. They were available relatively late. The decision as to which case was to receive penicillin was decided by the toss of a coin—thus ensuring random selection. The only exceptions to this procedure were four of the hypertoxic cases. A total dosage of 200 pastilles over a period of five days was aimed at. The pastilles were held in the side of the mouth without sucking and continuously renewed. Twenty-four of the penicillin cases and 34 of the control series had been observed up to the 45th day and the number still with positive throats at 5-day intervals was ascertained. Examination of Table X shows that the num-

TABLE X

Day	1	15	20	25	30	35	40	45
Penicillin	24	8	4	3	2	1	1	1
Control	34	15	12	9	8	7	7	5

bers fell off in geometric proportion, as would be expected from general considerations and from the work of Hartley and Martin (1919-20). Hence, taking the logarithm of these figures, we got two series, the relation of which to time could be quite adequately represented by straight lines.

(see Graph) Regression lines were calculated by the method of least squares, and gave the following formulae

Letting y = number carrying on any particular day
Letting x = the particular day

Penicillin $\log_{10} y = 1.3529 - 0.03391x$
Control $\log_{10} y = 1.4696 - 0.01765x$

The first figure to the right of the equation is a function purely of the number of cases in each group. The second figure is an estimate, in the form of a regression coefficient, of the logarithm of the rate of clearance of each particular group—a figure which varies from epidemic to epidemic. The difference between these two regression coefficients—0.01627—is an index of the difference in rate of clearance between the two groups. This figure can be shown to be highly significant statistically, its standard error being 0.003338, giving a "t" of 4.88 and a probability for 12 degrees of freedom which is less than 0.001. The figures compare favourably with the formula obtained by Hartley and Martin

$$\text{Log}_{10} y = 2.6002 - 0.0218 x$$

The statistical methods were derived from Fisher (1944), and Yates's correction for continuity was used throughout in the estimation of χ^2 .

Discussion

This epidemic has been described because it is felt that it is comparatively unusual in four points—namely, the short duration before admission, the large serum doses used, the age group covered, and the use of penicillin pastilles.

The short duration of symptoms before admission demonstrates the value of brief educational talks during epidemic periods. From the figures, prompt administration of an adequate dosage of serum does not appear to play any great part in preventing the development of palatal paresis, although it may limit the neurological involvement. On the other hand, it is felt that the low incidence and comparative triviality of the circulatory changes may be the result of the treatment. With regard to factors operating in the development of neurological complications this series is not ideal for studying the effects of duration of symptoms prior to admission, as the majority were seen on the first or second day. The fact that we are dealing with an adult population, presumably partially immune, is reflected in the difficulty of diagnosis of early cases. The comparatively late development of membrane in the partially immune has been pointed out by Neubauer (1943), who also noticed that exudate was readily wiped off without bleeding. That a number of cases later progressed to membrane formation indicates that the appearance of follicular and confluent exudate is a stage in the development of membrane. Pallor of mucous membrane was of little diagnostic use in this epidemic, as 40% had a concomitant streptococcal infection.

The series receiving penicillin was small, but the results are statistically quite definite, and it can be assumed that penicillin pastilles are effective in increasing the rate of clearance. A number of late carriers were also treated with penicillin pastilles. The impression was formed that it was much less effective in this type of case, but the numbers treated were too small to be certain of this.

Summary

An epidemic of diphtheria in adults has been described notable for the short duration of symptoms before admission. Difficulties of diagnosis have been discussed and the results of a short series of cases treated with penicillin have been given.

We are indebted to the Director of Medical Services for permission to publish this paper. We wish to thank Brig E. Bulmer, late R.A.M.C., and Lieut-Col W. Melville Arnott, R.A.M.C., for assistance, interest, and encouragement during the course of the investigation, and the nursing and medical staff—particularly Capt. Fitzpatrick, R.A.M.C.—for their thoroughness and care in dealing with the patients.

PENICILLIN IN THE TREATMENT OF DIPHTHERIA

BY

M. N. DE, MB, MRCP

AND

L. GANGULI, MB, BSc

Senior House physician, Medical College Hospitals, Calcutta

Diphtheria is one of the commonest causes of death among young children, and before the days of antitoxic serum it had a staggering mortality. Antitoxin has no doubt greatly reduced its mortality rate, nevertheless, it remains the most dangerous infectious disease to children. The sensitivity of *Corynebacterium diphtheriae* to penicillin is well known, but the therapeutic value of penicillin in diphtheria has not yet been ascertained.

Review of Literature

Christic and Preston (1946) reported two cases of malignant diphtheria with bull-neck treated with heavy doses of antitoxic serum and penicillin; one patient died and the other recovered. Richard J. Dodds (1946) reported 13 cases of diphtheria treated successfully with systemic penicillin in addition to normal doses of antitoxin. Ercoli, Lewis, and Moench (1945) reported experiments in which penicillin in a concentration of just over 1 unit per ml inhibited *C. diphtheriae* *in vitro*. They induced experimental bacteraemia in mice by intraperitoneal injection of *C. diphtheriae* mixed with mucin. Subsequent injections of penicillin or sulphadiazine overcame the bacteraemia. However, when toxin was injected subcutaneously into rabbits or guinea-pigs it could not be counteracted by penicillin. A small inoculum of bacilli injected into guinea-pigs produced a local lesion with toxæmia just like human infection. In such cases they found that penicillin had negligible action. These observers concluded that penicillin might be of slight benefit in the prophylaxis of exposed contacts but that it could have no appreciable value in the treatment of patients suffering from clinical diphtheria, for which antitoxin should be given without any delay.

Penicillin in the treatment of diphtheria carriers appears to have been tried successfully by Berman and Spitz (1945). They treated 10 diphtheria carriers with penicillin solution containing 500 units per ml four times daily. 1 ml of this solution was instilled into each nostril and 1 ml was sprayed into the throat with an atomizer. Within five days all reverted to a non-carrier state, whereas with a control group this took five to seven weeks. These observers believe that penicillin offers a quick and simple solution to the problem of diphtheria carriers. The fact that the organisms disappear quickly from the nasopharynx indicates that penicillin may be used as an adjunct in the treatment of clinical diphtheria. The replacement of antitoxin by penicillin, however, is not advocated.

It will be seen that there is no report of the use of penicillin without antitoxic serum in the treatment of clinical diphtheria. A trial of this nature is no doubt fraught with risk, as penicillin, although effective against *C. diphtheriae*, has no action on its toxin. The present study was undertaken with a view to ascertaining whether the drug can be used alone in place of the serum. The risk has been minimized by selecting early cases under the assumption that

the child can destroy and/or eliminate a certain amount of diphtheria toxin. A few moderately severe cases have also been treated, but we kept a very close watch on them for development of bad symptoms.

The following facts should be kept in mind when conducting a clinical trial of penicillin in diphtheria: (1) That the main cause of death in diphtheria is the injurious action of the powerful exotoxin secreted by *C. diphtheriae* on the circulatory and nervous systems, and that the therapeutic value of antitoxic serum is due to its ability to neutralize this exotoxin, on which penicillin has no direct effect. (2) That there are cases of diphtheria in which death is due to asphyxia caused by mechanical obstruction of the air passage by the diphtheritic pseudomembrane. Penicillin by exerting its lethal effect on *C. diphtheriae* may be able to check further formation and spread of such membranes when it is used early enough. (3) That the role of secondary respiratory infections in increasing the mortality in diphtheria is not insignificant, and penicillin may be a valuable therapeutic agent against such infections.

Method

For the sake of convenience the series was divided into four groups. Only penicillin was given in each case, the mode of administration in all cases being as follows:

A solution of a sodium salt of penicillin containing 100,000 units in 20 ml of sterile normal saline was used. Of this solution 2 ml (containing 10,000 units) was injected intramuscularly every three hours using a 2-ml syringe that had been sterilized by boiling, the penicillin solution being kept in a refrigerator. The time for stopping the penicillin injections was determined by the following factors: (1) the fall of temperature and pulse rate to normal level, (2) the disappearance of the pseudomembrane, and (3) three consecutive negative swab cultures taken daily. The minimum period of treatment with penicillin was four days and the maximum period seven teen days. It will be evident from the case reports that the injections of penicillin were continued longer than necessary. In many of the earlier cases penicillin was given even when the patch had disappeared and the throat swab had become bacteriologically negative. This was due to our ignorance about the dose necessarily effective in diphtheria. We were trying to cover a new field of clinical investigation, which we were afraid might be injurious to the patients. Hence, when treatment with penicillin was first started in August, 1945, the drug was given for a period probably longer than necessary, this was just to be on the safe side. Later it was found that there was no need to continue penicillin when the patch cleared up and the swab became negative.

Classification into Groups

Group I Early Cases, Bacteriologically Positive—There were 12 cases (8 females and 4 males), 11 were Hindus and 1 a Muslim, their ages varied from 8 months to 11 years. They had had fever and sore throat for two to six days. The temperature ranged from 99° to 104° F (37.2°–40° C) and the general condition was good. They had either a small patch on one or both tonsils or a moderate sized patch on one tonsil. Before starting penicillin injections throat and nasal swabs were taken and inoculated immediately on the spot into Dorset's egg medium or Loeffler's serum medium. Within 48 hours the temperature dropped to normal in seven cases and within three to six days in the rest. The patches cleared up completely within two to five days. The throat swabs became negative in three to seven days after treatment was started, the total dose of penicillin required varying from 390,000 to 510,000 units. The patients were kept in hospital for one to four weeks but had no complications so were discharged as cured and parents were asked to report every week if any complication occurred. One of the patients had an attack of non-diphtheritic sore throat about a week after discharge.

This was successfully treated with sulphonamides, and tonsillectomy was advised. No bad report was received from the remaining cases.

Group II Early Cases, Bacteriologically Negative but Clinically Diagnosed as Classical Diphtheria—There were eight such cases—all Hindu boys aged from 10 months to 6½ years. They came with a history of slight fever and cough of one to four days' duration. They had a small patch on one or both tonsils, a moderate-sized patch on one tonsil, or a small patch on one tonsil and another small patch on the uvula. The patches had all the characteristics of diphtheritic membrane, and so they were diagnosed as classical diphtheria. Their rectal temperature varied from 99° to 102° F (37.2° to 38.9° C) and their general condition was good. Before starting treatment throat and nasal swabs were inoculated into culture media. Within 72 hours the temperature dropped to normal except in one case where the temperature fell to normal on the sixth day. Within two to three days the patches cleared up completely. The throat and nasal swabs were negative from the beginning. Two patients who had received 480,000 and 560,000 units of penicillin were discharged at the request of their parents after a week's stay in hospital, and the parents were instructed to report if complications occurred at home. Another patient had had 480,000 units of penicillin when his parents took him away on risk bond. At the time of discharge he was doing well and there was no trace of a patch in the throat. The remaining cases had 320,000 and 400,000 units of penicillin and were discharged after two to four weeks.

Group III Moderately Severe Cases, Bacteriologically Positive—There were four of these cases—two Hindu boys aged 3 and 4 years and two Muslim girls aged 3. They had had a fever and sore throat for six or seven days. One had slight suction. Three had large patches on both tonsils and a small one on the uvula, one had small patches on both tonsils, with bleeding from the nose and enlarged cervical and maxillary lymph nodes. Two were slightly toxic. After taking nasal and throat swabs penicillin was started. Within three to six days the temperature fell to normal, with improvement of the pulse rate and disappearance of the patch. Throat swabs were negative in three days in two cases, in five days in one, and in six days in the other. They received 400,000, 480,000, 720,000, and 1,190,000 units of penicillin. They were kept under observation for four weeks without there being any complication and were then discharged as cured. No report of any complication has been received.

Group IV Moderately Severe Cases, Bacteriologically Negative but Clinically Diagnosed as Classical Diphtheria—In this group there were three cases—two boys and one girl, all were Hindus, their ages being 1, 2½, and 3 years. They came with a history of fever and sore throat of three to seven days' duration. They were slightly toxic, the temperature varying from 99° to 101° F (37.2° to 38.3° C). One had a moderate-sized patch on each tonsil; the second had a moderate-sized patch on the tonsils and uvula, hoarseness of voice, and slight difficulty in breathing, and the third had one moderate-sized patch on the left tonsil and another in the pharynx. The patches had all the typical characteristics of diphtheritic membranes. Throat and nasal swabs were inoculated before any treatment was started. Within one to three days the temperature came down to normal. The patches cleared up in two to three days. Suction and hoarseness of voice disappeared next day. The patients received 360,000, 365,000 and 400,000 units of penicillin. Two of them were kept in the hospital for four and five weeks without any complication and were then discharged as cured. The third stayed for

two weeks, and was reported to be keeping well a fortnight after discharge from hospital

Case Reports

Case 1—A female Hindu child aged 4 was admitted on Sept 5, 1945, with a history of fever and sore throat for six days. General condition fair. Temperature 99° F (37.2° C), pulse 120, respirations 24. Small patch on left tonsil and another on tip of uvula. Throat swab positive. Temperature fell to normal within 48 hours, patch cleared up within five days, swab became negative in seven days. Total dose of penicillin, 960,000 units. No complications. Discharged on Sept 17 at request of parents. No bad report received.

Case 2—A female Hindu child aged 1 was admitted on Sept 10, 1945, with a history of fever and sore throat for four days. General condition fair. Temperature 99° F, pulse 125, respirations 24. Tonsils congested and enlarged, patch on both tonsils. Throat swab positive. Temperature dropped to normal within 48 hours, patch cleared up in three days, swab became negative in five days. Total dose of penicillin, 560,000 units. No complications. Discharged on risk bond on Sept 17. No bad report received since.

Case 3—A male Hindu child aged 2½ was admitted on Sept 10, 1945, with a history of fever and sore throat for five days. General condition fair. Temperature 99° F, pulse 110, respirations 24. Tonsils enlarged, patch on left tonsil. Throat swab positive. Temperature fell to normal in 24 hours, patch cleared up in two days, swab became negative in three days. Penicillin was stopped on Sept 19. Total dose, 720,000 units. No complications. Discharged on Sept 21. Had an attack of non-diphtheritic sore throat, treated successfully with a sulphonamide and was advised to have tonsillectomy afterwards.

Case 4—A female Hindu child aged 10 was admitted on Nov 14, 1945, with history of fever and sore throat for two days. General condition fair. Temperature 102° F (38.9° C), pulse 135, respirations 32. Tonsils enlarged, patch on both tonsils. Throat swab positive. Temperature fell to normal within 36 hours, patch cleared up in two days, swab became negative in three days. Penicillin stopped on Nov 22. Total dose, 640,000 units. No complications. Discharged on Nov 23. No bad report received since.

Case 5—A female Muslim child aged 3 was admitted on March 27, 1946, with a history of fever and sore throat for six days and otorrhoea for two days. General condition fair. Temperature 102° F, pulse 126, respirations 30. Tonsils much enlarged, patch on both tonsils. Nose blocked with dry blood clot at the nares. Small furuncles in left external ear, which was discharging pus. Cervical lymph nodes enlarged. Throat swab positive, ear and nasal swabs negative. Temperature dropped to normal within three days, patch cleared up in four days, swab became negative in five days. Bleeding from nose stopped in two days. Penicillin was stopped on April 2. Total dose, 480,000 units. No complications. Discharged on April 24. Everything normal except slight discharge from left ear.

Case 6—A male Hindu child aged 10 months was admitted on Sept 10, 1945, with a history of fever and sore throat for two days. General condition fair. Temperature 100° F (37.8° C), pulse 130, respirations 30. Tonsils enlarged, one small patch on left tonsil and another on uvula. Throat swab negative. Temperature dropped to normal in 72 hours, patch cleared up in two days. On Sept 15, the day of discharge, his throat was clear. Total dose of penicillin, 480,000 units.

Case 7—A male Hindu child aged 6 was admitted on Sept 12, 1945, with a history of fever and sore throat for two days. General condition fair. Temperature 100° F, pulse 112, respirations 24. Tonsils enlarged, small patch on left tonsil. Throat swab negative. Temperature fell to normal within 72 hours, patch cleared up in three days. Penicillin stopped on Sept 19. Total dose, 560,000 units. No complications. Discharged on Sept 21 at request of parents. No bad report received since discharge.

Case 8—A male Hindu child aged 1½ was admitted on Nov 21, 1945, with a history of fever and sore throat for one day. General condition fair. Temperature 100° F, pulse

134, respirations 32. Tonsils enlarged, small patch on both tonsils. Throat swab negative. Temperature fell to normal within three days, patch cleared up in two days. Penicillin stopped on Nov 27. Total dose, 480,000 units. No complications. Discharged on Nov 28 at request of parents. No bad report received since discharge.

Case 9—A male Hindu child aged 6½ was admitted on April 22, 1946, with a history of fever and sore throat for one day. General condition fair. Temperature 102° F, pulse 120, respirations 26. Small patch on both tonsils. A few rhonchi in lungs. Throat swab negative. Temperature dropped to normal in three days, patch cleared up in three days. Penicillin stopped on April 27. Total dose, 400,000 units. No complications. Discharged on May 4. No bad reports received since.

Case 10—A male Hindu child aged 1 year was admitted on April 24, 1946, with a history of fever and sore throat for four days. General condition fair. Temperature 100° F, pulse 135, respirations 30. Patch on left tonsil. Throat swab negative. Temperature dropped to normal within three days, patch cleared up in three days. Penicillin stopped on April 28. Total dose, 320,000 units. No complications. Discharged on May 5. No bad report received since.

Case 11—A male Hindu child aged 3 was admitted on Aug 6, 1945, with a history of fever and sore throat for seven days. Slightly toxic. Temperature 103° F (39.4° C), pulse 140, respirations 28. Moderate sized patch on tonsils and uvula. Throat swab positive. Submaxillary lymph glands enlarged and tender. Temperature fell to normal within 72 hours, patch cleared up in three days, swab became negative after five days, the glands subsided in five days. Penicillin stopped on Aug 15. Total dose, 720,000 units. No complications. Discharged on Aug 30. Reported to be keeping well a fortnight later.

Case 12—A female Muslim child aged 2 was admitted on Aug 22, 1945 with a history of fever and sore throat for seven days. Slightly toxic. Temperature 102° F (38.9° C), pulse 150, respirations 32. Slight suction. Moderate sized patch on tonsils and uvula. Throat swab positive. Temperature dropped to normal within three days, patch cleared up in four days, swab became negative after six days. On Aug 25 penicillin had to be stopped owing to lack of supply. The temperature again shot up. Penicillin restarted on Aug 27 and temperature fell to normal on Sept 5. After this she had an uneventful recovery. Penicillin stopped on Sept 11. Total dose, 1,190,000 units. Discharged on Sept 25. No bad report received since.

Case 13—A male Hindu child aged 3 was admitted on Aug 10, 1945, with a history of fever and sore throat for seven days. Slightly toxic. Temperature 99° F (37.2° C), pulse 125, respirations 28. Moderate sized patch on both tonsils. Throat swab negative. Temperature dropped to normal within 24 hours, patch cleared up in two days. Penicillin stopped on Aug 14. Total dose, 365,000 units. No complications. Discharged on Sept 17. No bad report received.

Case 14—A female Hindu child aged 2½ was admitted on April 7, 1946, with a history of fever and sore throat for three days. Temperature 100° F (37.8° C), pulse 140, respirations 35. Slightly toxic. Voice hoarse. Slight suction present, cervical lymph glands enlarged. Moderate sized patch on tonsils and uvula. Throat swab negative. Temperature dropped to normal within 48 hours, patches cleared up within three days. The suction and hoarseness of voice disappeared on the fourth day and the glands subsided within five days. On April 24 she developed slight pyrexia (99–100° F (37.2–37.8° C)), which continued intermittently till April 30. No local signs could be detected to account for fever. She was discharged on risk bond on May 2. Penicillin was stopped on April 12. Total dose, 400,000 units. No bad report received since discharge from hospital.

Case 15—A male Hindu child aged 1 year was admitted, on April 15, 1946, with a history of fever and sore throat for four days. Temperature 100° F, pulse 130, respirations 38. Slightly toxic. Moderate-sized patch on left tonsil and another on pharynx. Throat swab negative. Temperature fell to normal within three days, the patch cleared up in three days. On April 22 he developed slight pyrexia, which con-

intermittently for about a week. No local sign could be found to account for fever. Temperature normal on May 2. He was discharged on risk bond on May 3. Penicillin was stopped on April 19. Total dose, 360,000 units. Reported to be keeping fit a fortnight after discharge.

Case 16—A Hindu female child aged 7 was admitted on Sept 25, 1946, with history of fever for two days, pain in throat, and difficulty in deglutition. Anaemia present. Neck glands enlarged both sides. Tonsils enlarged, with moderate-sized patches. Throat swab positive. Temperature 99.6° F (37.55° C), pulse 124, respirations 32. Temperature dropped to normal within 48 hours. Patch cleared up within five days. Total dose of penicillin, 485,000 units. Discharged on Oct 31. No complications.

Case 17—A Hindu male child aged 11 was admitted on Sept 4, 1946, with history of painful throat and difficulty in deglutition for two to three days. No history of fever. General condition fair. Temperature 98.4° F (36.9° C), pulse 88, respirations 24. Moderate sized patch on both tonsils. Throat swab positive. Patches disappeared on fourth day. Throat swab negative after two days. Total dose of penicillin, 390,000 units. No complications. Discharged on Sept 26.

Case 18—A Hindu female child aged 10 was admitted on Aug 2, 1946, with a history of fever for four days, difficulty in deglutition for two days, and painful throat. General condition fair. Moderate sized patch on right tonsil and small one on left tonsil. Temperature 99° F (37.2° C), pulse 110, respirations 26. Cervical lymph nodes enlarged and tender. Throat swab positive. Temperature fell to normal on third day. Patch disappeared on fourth day. Throat swab negative on third day. Total dose of penicillin, 430,000 units. No complications. Discharged on Aug 27.

Case 19—A Hindu male child aged 6 was admitted on July 31, 1946, with history of fever and sore throat for seven days. General condition fair. Moderate sized patch on both tonsils. Temperature 104° F (40° C), pulse 134, respirations 32. Throat swab positive. Temperature reached normal level on fifth day. No patch detected on fourth day. Throat swab negative on third day. Total dose of penicillin, 510,000 units. No complications. Discharged on Aug 27.

Case 20—A Hindu female child aged 7 was admitted on Sept 2, 1946, with a history of fever and sore throat for one day. Moderate sized patch on left tonsil and small one on the right. General condition good. Throat swab positive. Temperature 103° F (39.4° C), pulse 140, respirations 32. Temperature fell to normal on seventh day. Patch disappeared on fifth day. Throat swab negative on second day. Total dose of penicillin, 460,000 units. No complications. Discharged on Sept 26.

Case 21—A Hindu male child aged 8 months was admitted on July 17, 1946, with a history of fever and cough for eight days and reluctance to feed for the last three days. General condition fair. Small patch on left tonsil. Temperature 100° F, pulse 122, respirations 24. There was also extensive impetigo. Throat swab positive. Temperature came down to normal on fifth day. Patch disappeared on fourth day and throat swab negative on third day. Total dose of penicillin, 470,000 units. No complications. Discharged on Aug 23.

Case 22—A Muslim female child aged 3 was admitted on March 7, 1946, with a history of fever for six days, difficulty in breathing for four days and difficulty in deglutition and painful throat for four days. Tonsils very much enlarged and covered with several small thin patches. Cervical and submaxillary lymph glands of both sides were enlarged. Temperature 103.8° F (39.9° C), pulse 122, respirations 32. Throat swab positive. Temperature reached normal level on third day. Patch disappeared on fifth day and throat swab became negative on third day. Total dose of penicillin, 480,000 units. No complications. Discharged on April 24.

Case 23—A Hindu male child aged 4 was admitted on Nov 1, 1946, with history of fever and cough for two days and slight difficulty in breathing. General condition fair. Tonsils enlarged. Moderate-sized patch on right tonsil, extending down towards the larynx, a small crescentic patch on left tonsil and a small patch on the uvula. Temperature 100° F, pulse 110, respirations 36. Throat swab positive.

Temperature reached normal level on sixth day, patch disappeared on fifth day. Throat swab negative on third day. Total dose of penicillin, 400,000 units. Discharged on Dec 4.

Case 24—A Hindu child aged 8 months was admitted on Aug 2, 1946, with a history of fever for one day, with excessive salivation. General condition fair. Small patch on right tonsil. Temperature 100° F, pulse 130, respirations 30. Throat swab positive. Temperature fell to normal on fourth day. No patch on throat on third day. Throat swab negative after second day. Total dose of penicillin, 390,000 units. No complications. Discharged on Aug 22.

Case 25—A Hindu male child aged 6½ was admitted on April 22, 1946, with a history of fever and painful throat for one day. General condition good. Small patch on both tonsils. Temperature 102° F (38.9° C), pulse 140, respirations 20. Throat swab negative. Temperature fell to normal on third day. Patch disappeared on third day. Total dose of penicillin, 400,000 units. No complications. Discharged on May 4.

Case 26—A Hindu male child aged 1 year was admitted on April 24, 1946, with history of cough and fever for four days. General condition fair. Small patch on both tonsils. Glands of neck enlarged. Temperature 101.4° F (38.55° C), pulse 120, respirations 30. Throat swab negative. Temperature fell to normal on sixth day. Patch disappeared on third day. Total dose of penicillin, 400,000 units. No complications. Discharged on May 2 on request.

Case 27—A male Hindu child aged 2½ was admitted on June 27, 1946, with a history of fever, cough, and excessive salivation for two days. A 1/4-in (6-mm) circular patch was seen on right tonsil. General condition fair. Temperature 102° F, pulse 134, respirations 26. Throat swab negative. Temperature fell to normal within 72 hours. No patch was seen next morning but a raw ulcer area was found on right tonsil persisting up to fourth day. Total dose of penicillin 210,000 units. No complications. Discharged on July 13.

Discussion

As only 27 cases were treated with penicillin it would be unsafe to draw any definite conclusion from the results of treatment. Still, it would not be out of place to discuss a few points regarding the merits and demerits of such treatment. As no antitoxic serum was used, only early cases or moderately severe cases with slight toxæmia were selected, for obvious reasons. Of the 27 cases 16 were bacteriologically positive, and the remaining 11, though bacteriologically negative, were clinically diagnosed as diphtheria. In the majority the temperature dropped to normal within one to three days. In diphtheria treated with antitoxic serum the temperature usually takes longer to fall to normal, this may, of course, be due to the fact that when large quantities of antitoxic serum (animal serum) are injected, the serum itself prolongs the raised temperature. In all cases the general condition greatly improved within three days, and in those cases in which this was good at the start of treatment it never deteriorated with the progress of the disease. Even the extensive patches affecting the tonsils, uvula, pharynx, and larynx disappeared within five days and the small patches within one to two days. Treatment with antitoxic serum does not heal the patch so quickly, usually it takes a week or more to clear an extensive patch. The bacteriostatic (and probably bactericidal) effect of penicillin may help to clear the patch and thereby quickly remove the source of exotoxin formation. This factor may have a definite influence on the ultimate prognosis of the disease. In all the 16 cases which were bacteriologically positive the swab became negative within six days. This is rather quick compared with the results in antitoxin therapy, where it takes more than a week, sometimes weeks, before the swabs become negative. Extension of the patch after starting the treatment was never noticed. In the present series of cases complications were singularly absent. The circulatory and nervous complications which are the

direct effect of diphtheritic toxin were absent, and so were the respiratory complications which are mainly due to secondary organisms. Tracheotomy was not necessary in any of the cases, though two of them were admitted with slight suction, of course such a result could be obtained with antitoxic serum. Not a single death occurred in the present series.

The mortality rate for diphtheria at the Medical College Hospitals, Calcutta, during the five-year period from 1941 to 1945 varied from 20 to 36%. The lowest (20.3%) occurred in 1941 and 1945, and the highest (36.5%) in 1944. The average mortality was 25.6%—total admissions, 1,429, deaths, 366. In the present series the mortality was nil, but we must keep in mind that of the 27 cases 20 were mild and 7 moderately advanced. From such a small number of cases we cannot assess the value of penicillin in the treatment of diphtheria, but we feel that the subject requires further study. Penicillin cannot replace antitoxic serum in severe cases of diphtheria where immediate neutralization of toxin is imperative, but is it possible to treat early cases with penicillin alone? Diphtheria confers a good deal of immunity to the sufferers who survive. For the production of active immunity we often have recourse to injections of modified toxin such as TAF and T.A.M. or A.P.T. Now if an early case of diphtheria is treated with penicillin alone the infection may be checked, and at the same time the amount of toxin absorbed in the system will be partly destroyed and partly used up as an antigen. Can this toxin act as a stimulus for the production of a better type of immunity? The answer should be 'yes,' as we know that the best way to acquire immunity is to suffer from the disease in a mild non-fatal form. Incidentally, it may be mentioned that prophylactic immunization is practically not done in India as a routine.

The disadvantage to a child of three-hourly injections of penicillin should be kept in mind. It is distressing to the patient, and the parents will often object. Whether this disadvantage will be overcome by the discovery of a preparation such as penicillin in beeswax and peanut oil or by the injection of a single large dose of penicillin, as has been tried successfully in some cases of gonorrhoea, is still a matter of speculation, but such possibilities cannot be disregarded. Whether penicillin in conjunction with antitoxic serum can reduce the mortality rate and the incidence of complications in severe cases of diphtheria is also a subject that needs intensive study.

The financial aspect must also be considered. We have shown that the average curative dose of penicillin is within the limit of 500,000 units. In this institution an average curative dose of antidiphtheritic serum for a similar group of cases was 50,000 to 60,000 units. When we started to use penicillin therapeutically in the middle of 1945, the drug was scarce and the price varied from Rs 20 to Rs 15 (£1 10s to £1 2s 6d) for each phial of 100,000 units. At the end of 1946 the price was Rs 3/8 (5s 3d) for 200,000 units, and the supply was ample. The price of antidiphtheritic serum in the middle of 1945 was between Rs 6 and Rs 7 (9s and 10s 6d) for 10,000 units. The present price is Rs 7 (10s 6d) for 10,000 units. Thus the cost for each case treated with penicillin is Rs 8/8 (12s 9d) and for each case treated with antidiphtheritic serum Rs 35 to Rs 42 (£2 12s 6d to £3 3s). We expect the price of penicillin to fall still further. This reduction in cost is at present possible only in an institution where there is a whole-time staff and nurses to attend to the patients. In private practice the patient will have to bear the additional cost of continuous medical attendance for three-hourly injections, careful nursing, and the storage of penicillin, particularly in tropical climates.

Summary

Twenty seven cases of diphtheria treated with penicillin alone are reported. 16 were bacteriologically positive and 11, though bacteriologically negative, were clinically typical cases of diphtheria. Twenty were early and seven moderately severe.

All the cases recovered without developing any complications, the temperature was normal within three days the throat swabs became negative within three to seven days, and the patches disappeared within two to five days.

The merits and demerits of penicillin in diphtheria and the possibility of future improvement are discussed. Penicillin treatment is undoubtedly more economical.

Typing of the particular strain was not ascertained. Only the clinical aspect of the cases is mentioned.

Our thanks are due to Prof. B. P. Trivedi for his ungrudging help in bacteriological matters, and to the Superintendent, Medical College Hospitals, Calcutta, for kindly allowing us to use the hospital records in preparing the article and for supplying us with penicillin.

A CASE OF MESENTERIC THROMBOSIS COMPLICATING MULTIPLE WOUNDS RECOVERY FOLLOWING MASSIVE RESECTION

BY

W. N. HINE, M.C., M.R.C.S.

Late Major Surgical Specialist R.A.M.C.

Mesenteric thrombosis is a catastrophe that seldom occurs in men of military age. The following case history has an added interest because its aetiology is difficult to dissociate from the consequence of severe shell wounds sustained nearly four months previously.

Case Report

A trooper of the Royal Tank Corps aged 32 had enjoyed excellent health until he was wounded in action on Jan. 31, 1944. Severe injuries to both lower limbs necessitated transfusion and prolonged resuscitation before wound toilet was performed on Feb. 2. Secondary haemorrhage arose from an extensive infected wound in the left thigh on Feb. 12, and was controlled by ligation of the femoral artery in Hunter's canal. He then progressed satisfactorily until March 1, when a wound in the neighbourhood of the right knee-joint was found to have caused suppurative arthritis. This demanded wide incisions and splinting with strapping extension.

The patient first came under my care at the 67th British General Hospital on May 5, 1944. His general condition was very satisfactory and no disease of heart or lungs was noted. Temperature, pulse, and respirations remained normal. The plasters were changed. The wounds of the left thigh and leg were healed and a fracture of the left tibia had united. The right knee joint was still slightly swollen and the drainage incisions were granulating. Quadriceps exercises were performed daily.

Occurrence of Thrombosis.—At 4 a.m. on May 27 the patient was awakened by abdominal pain, and after expressing a desire to defaecate, he attempted unsuccessfully to use a bed pan. Vomiting then occurred, and collapse was evidenced by increasing subnormal temperature, and a rapid thready pulse. The abdomen moved with respiration and tenderness was limited to a circular area 6 in. (15 cm.) in diameter around umbilicus. Morphine, 1/4 gr. (16 mg.), was administered and plasma drip was started. At 8 a.m., although the degree

collapse was less profound pain had greatly increased. It was spasmodic in character, causing him to cry out and to grip his abdominal wall. Generalized abdominal rigidity was noted during the attacks of pain, but in the intervals guarding was only apparent around the umbilicus, there was no visible peristalsis and the abdomen was silent on auscultation. Lieut Col W Brindle, R A M C was called in consultation and made a diagnosis of mesenteric thrombosis. He recommended surgical intervention. By 10 a.m., after administration of 2½ pints (1.42 l) of plasma, the patient's general condition improved, his pulse rate was 110 and his blood pressure 98/70.

Operation—Major Ward, R A M C induced anaesthesia with 0.5 g of thiopentone and continued with gas and oxygen. In addition the tissues of the abdominal wall were infiltrated with 2% novocain. A midline incision extending 4 in (10 cm) above and below the umbilicus was employed, and on incising the peritoneum much blood-stained fluid escaped. Distended coils of chocolate coloured small intestine with oedematous haemorrhagic mesentery presented and were delivered from the wound. The peritoneal coat of the damaged gut still retained the normal sheen, but the upper and lower limits of devitalization were sharply demarcated. Bowel clamps were applied to healthy intestine 2 in (5 cm) above and below the involved segment and resection was rapidly performed. The mesentery was clamped and removed at its base beyond the areas of most intense haemorrhage. In all 91 in (231 cm) of gut was removed, and repair was effected by means of an end-to-end anastomosis. The omentum was sutured around the junction and over the mesenteric stump. The abdominal cavity was then mopped dry, and the abdominal wall was closed in layers without drainage.

Post operative Treatment and Progress—Continuous gastric suction was instituted and 2 pints (1.14 l) of whole blood was administered. Injections of morphine 1/4 gr (16 mg) were given four-hourly during the first 24 hours. By the following day the patient's general condition was much improved. His haemoglobin was 98%, pulse 120, temperature 100 F (37.8° C). Intravenous glucose saline introducing 2 g of sulphapyridine during each period of four hours was given by the drip method. Frequent sips of water were allowed, and although the bulk of this fluid was withdrawn by suction it helped to keep the mouth moist and relieved his thirst. The bowel acted satisfactorily four days after operation and gastric suction was discontinued on May 31. On June 13 after an apparently smooth convalescence, he complained of pain in the right iliac fossa and next day it was necessary to open a small abscess which had pointed in this region. Subsequently his progress was uninterrupted, and when he was evacuated to England on July 2 his condition was very satisfactory. He found no difficulty in digesting ordinary diet, and his stools were well formed and regular.

Follow up—On Sept 10 1944 I was informed by Maj Gen Ogilvie who examined the patient at a hospital in England that no further complications had arisen and that he appeared fit and well. He was also seen at Liverpool Hospital in 1945. He had made a full recovery and was doing light work.

I am most grateful to Lieut Col W Brindle, R A M C, for his advice and help in dealing with this case, and to Col A Angus M C Lieut R A M C for permission to publish this paper.

The Register of Ambulance Stations compiled by the Home Ambulance Service of the Order of St John and the British Red Cross Society gives the addresses and telephone numbers whence ambulances may be obtained throughout Great Britain. The Home Ambulance Service was set up in 1919 to provide a better means of transport for the sick and injured than those commonly available particularly in the country, where improvised cabs and wagons often had to be used. It now has 1,000 vehicles in service. The ambulances are provided by the Order and Society and the responsibility for running houses and maintaining them rests entirely with voluntary workers. Thus the smallest possible fee is charged to patients and those who cannot afford to pay receive free transport. In 1923 the Mobile X-ray Service was started, as complementary to the work undertaken by the ambulances to bring X-ray units to the bedridden and immobile. In 1926 the work of the ambulance service was supplemented by a first aid road service boxes of splints and bandages were set up at the roadside and have proved invaluable to the many victims of road accidents.

Medical Memoranda

A Case of Dislocation of the Metatarso-Tarsal Joints

The following case is of interest because of the rareness of the condition and the radical form of treatment adopted.

CASE REPORT

Miss A., aged 56, was first seen on Oct 10 1945. She fell a short distance down a step on to her right foot, which became swollen and very painful. Tenderness was most pronounced over the base of the first metatarsal. A radiograph showed a complete

Radiograph of both feet, Oct 10, 1945

lateral dislocation of the metatarso-tarsal joints, with a fracture of the first cuneiform at the base of the first metatarsal. Reduction in the out-patient department failed and she was admitted under my care on Oct 13. The following day a pin was inserted through the metatarsals, and a weight of 7 lb (3.1 kg), later increased to 10 lb (4.5 kg), was applied, the leg being bandaged to a Braun frame. This produced some distraction but no reduction and after two days manipulation under anaesthesia was performed with the weight in place. No real improvement was obtained. The pin was removed and after the skin had recovered from fairly severe blistering I performed the formal operation of arthrodesis of all metatarso-tarsal and inter-metatarsal joints on Oct 31. There was considerable fracturing of both metatarsal and tarsal bones which was not obvious in the radiograph. Plaster was applied and by March 16 1946 the patient was discharged, with no detectable clinical abnormality. Despite the extensive arthrodesis the foot was not less mobile than its fellow.

COMMENT

This fracture is not referred to by the majority of authors but Böhler (1935) mentions various tarso-metatarsal dislocations, of which those involving the first and fifth are the most common. He advises distraction, with a pin through the metatarsals and os calcis. This might have been successful, although I doubt it. The risk in such a method is persistent pain afterwards. If mobility is to be of great importance as in the subtalar joint it is a debatable question whether arthrodesis is the best treatment but in such a case as this it seems to me the ideal treatment, as mobility is minimal at these joints and there is little risk of persistent pain if the arthrodesis is successful.

An interesting case of fracture dislocation of the mid tarsal and cuboideo-navicular joints was reported recently by Jaslow (1946). This produced a rather similar picture but at a different level in the foot. His case was also treated by fixation, using a screw, with a completely satisfactory result. The very satisfactory result in my case suggests that arthrodesis as a primary measure is the best form of treatment.

MANUAL OF MALARIOLOGY

Practical Malarology By Paul F Russell, M.D., M.P.H., Luther S West, Ph.D., and Reginald D Minnwell, Sc.D. Prepared under the auspices of the Division of Medical Sciences of the National Research Council. Foreword by Raymond B Fosdick. (Pp 684, 238 illustrations 40s.) London and Philadelphia W B Saunders Company 1946

One of the outstanding features in the last war was the successful application of the results of years of research and increasing experience in malaria prevention to protecting our troops in some of the most malarious countries in the world. One reason for this success was the recognition by the higher military command of the importance of such measures and its active participation in seeing them carried out. Equally important was the extent to which medical men and others trained in malaria field work and skilled specialists have been forthcoming. Among the latter none stands higher than Paul F Russell of the International Health Board of the Rockefeller Foundation, one of the authors of *Practical Malarology*. Dr Russell, besides having spent many years in malaria research and prevention in the Philippines, in Malaya, and in India, was chief malarologist to the American Forces in North Africa and Italy during the war. He has been assisted in preparing the volume by Luther S West, of the Entomological Section and Reginald F Minnwell, of the Protozoological Section of the Parasitology Division of the United States Army Medical School.

Though published as a military manual the book has been written primarily for the civilian. In 684 pages it covers a wide field, as indeed it must do if it is to serve its purpose, for the practising malarologist has now to be conversant with the many aspects of malaria. Detailed information is what he requires more than anything else on, for example, the parasites of malaria, human, avian, and simian, the wide field of malarial epidemiology, various community indices, which bulk so largely in practical work, and on the different forms of control measures—methods of spraying, dusting, flushing, water covering pisciculture, and much else. There is also the important subject of the modern synthetic antimalarial drugs and the legal and social aspects of preventive work. The authors deal with all this fully, and give information about practical laboratory and field procedures and technique, the collection of eggs, larvae and adult mosquitoes, the taking of spleen and parasite indices, the precipitin reaction as used in determining the source of the blood feed of mosquitoes, cultural methods, and other modern laboratory techniques. Giemsa, Leishman, and other staining methods are described with formulae for making the stains. The section on mounting, preserving, and dissecting mosquitoes is particularly full and up to date, as is that on mixing and distributing dusts and sprays, which includes an account of DDT and its uses. At the end of each chapter is a list of references, in all over 600.

The book is well illustrated with many figures of modern apparatus and excellent photographs of breeding-places, etc. In an appendix are the synoptic tables for identification of the anopheles species of different countries. The book is in fact the most modern and complete account of practical laboratory and field work yet published.

RICKARD CHRISTOPHERS

A COMPENDIUM OF MEDICINE

Modern Management in Clinical Medicine By F Kenneth Albrecht, M.D. (Pp 1,238, illustrated 55s.) London: Bailière, Tindall and Cox 1946

The curious title does not properly describe this book, which is essentially a one-man encyclopaedia of medicine. The author was formerly director of a U.S. marine hospital, and his book is in the same class as French's *Differential Diagnosis* or Tidy's *Synopsis of Medicine*—the off-duty task of a busy and experienced clinician who is interested in organizing his knowledge and keeping it up to date. It is easy to condemn a book of this kind as all paste and scissors, but the fact remains that Dr Albrecht has done his self-imposed task surprisingly well.

He begins by considering the case history and then reviews the various systems in detail. Some of the sections, such as those on nutritional deficiency, peripheral vascular disease, the diagnosis and management of venereal diseases, arthritis, endocrinology, allergy, and geriatrics are much fuller and more practical than is usual in current textbooks. There are a chapter on clinical laboratory medicine and an appendix containing details of therapeutic procedures and diets. Throughout the book there are numerous tables and summaries which provide convenient reference to an astonishing amount of precise knowledge. If you want a sheet of instructions for almost any topic from fever therapy to bed bug control, from patch testing to a barium meal and follow through, you will be almost certain to find it here. There are numerous diagrams and photographs and some excellent coloured plates. The whole book runs to over 1,200 pages in double column yet remains manageable and easy to handle. Book reviewers have so often said "this book should be on every practitioner's shelf" that the statement has become suspect. We will therefore say that with Albrecht at his side the practitioner will never be nonplussed and will always have the most modern information on the problems he meets in his consulting room and his daily round.

L. J. WITTS

MANUAL OF PARENTHOOD

Parentcraft: A Handbook for Parents and Students Second edition (Pp 248 8s 6d.) London: National Association of Maternity and Child Welfare Centres and for the Prevention of Infant Mortality.

This is a second edition of a publication of the National Association of Maternity and Child Welfare Centres produced first in 1945 to replace *Mothercraft* which had been out of print for many years. In this book many authorities deal with various aspects of child welfare. The essays are grouped into four parts—the first dealing with the parents, the second with the child, the third with prevention and treatment of the common ailments of childhood, and the fourth with the social aspects of parentcraft, including eugenics, the care of the unmarried mother and her child, and the various social services concerned with childhood.

Much information is crammed into a small space, but in common with so many of such manuals the whole stress is laid on the physical side of the question, and the psychological is somewhat neglected. For example, in the discussion on breast feeding, except for the statement that the mother should give her whole attention to feeding her baby, there is not a word on the important psychological aspect of the "nursing couple". Even in Agatha Bowley's section it is disappointing to find that she does not make more of the emotional development of the child. Mr Kenneth Walker deals with some psychological questions in his section on preparation for marriage, but otherwise the information is severely materialistic. If it were not for this unfortunate lack of balance the book could be usefully recommended to all those dealing with the rearing of children.

TUMOURS OF THE HEART

Les Tumeurs et les Polypes du Cœur. Étude Anatomique Clinique By Dr Ivan Mahaim (Pp 568, illustrated. No price given.) Paris: Masson et Cie 1945

Readers of Dr Ivan Mahaim's fine monograph on lesions of the bundle of His, published in 1931, will welcome his new work *Les Tumeurs et les Polypes du Cœur*. The scanty attention which has been paid to these uncommon conditions is due in part to their incurability, but the author has made a correct diagnosis of tumour of the heart twenty-five times in the past fifteen years, and he feels that there is a possible future for surgical intervention. Gummatous and tuberculous lesions and hydatid cysts have been excluded from his series, which includes not only benign, malignant, and secondary growths of the heart and pericardium, but also the intracardiac polyp.

The polyp of the heart is the commonest of all these tumours and is most frequently found pedunculated in the left auricle where it may threaten occlusion of the mitral orifice. The author distinguishes the anatomical features of myxomatous polyps and scouts the thesis of Thorel that all these lesions derive from organization of thrombus. He proceeds to discuss the clinical features of the three types of mechanical a

which may occur embolism by fragments of polyp, obliteration of a cavity by progressive enlargement, and occlusion of a valvular orifice. Among benign non polypoid tumours of the heart Mahaim has included the rare lipoma and fibroma, and the angiosarcoma and rhabdomyosarcoma. The only malignant tumours of the heart among the 400 assembled from the literature are the varieties of sarcoma, which show a special predilection for the auricles, while the pericardium is often involved.

The author considers that there is among physicians an insufficient awareness of the circumstances which call for consideration of the diagnosis of cardiac tumour. Unexplained syncope, attacks of unusual variability of physical signs in valvular disease, pericardial effusions without obvious cause, and unexpected arterial emboli should all bring to mind the possibility of tumours in the pericardium, the heart, or its cavities. Thus arterial embolectomy or the induction of pneumopericardium may be important diagnostic procedures. Just as the clinical separation of the varieties of congenital cardiac defect has been followed by the discovery of surgical methods of treatment so may operative measures be found for the removal of polyps, once the physician has become more skilled and more certain of the diagnosis of these dangerous lesions.

Dr Mahaim's excellent treatise is essentially for the cardiologist who will be interested and stimulated by it.

AN AMERICAN "BURDETT"

The American Hospital By E. H. L. Corwin, Ph.D. (Pp. 242, 8s. 6d. net). The Commonwealth Fund, London. Geoffrey Cumberlege.

The hospital service is now one of the major industries of the United States. It owns \$½ billion dollars worth of property (\$ billion in the French meaning of one thousand millions), its operating costs are 1½ billion dollars a year, and the principal stockholder is the American public. *The American Hospital*, one of the studies brought out by the New York Academy of Medicine Committee on Medicine and the Changing Order, is a careful survey of this hospital domain. In the United States there is one hospital bed (or cot) to about every 80 of the population, and every year one person in about ten is admitted as an inpatient. In 1940—the last pre-war year for America—71% of all hospital beds were maintained by Government, that is to say by Federal, State, county, or city, authorities, and 29% were in hospitals supported by religious denominations, lay voluntary hospitals and proprietary hospitals. One could quote figures endlessly on the finance of the hospitals and the distribution and utilization of their resources. One point only can be mentioned in a brief review. It has always been a tradition in the United States that apart from whole-time officers, all physicians, surgeons, and specialists attached to hospitals should be unpaid. The experience gained in hospitals and the prestige of association with them was thought sufficient reward. This practice has held good alike for tax-supported and for voluntary hospitals, and it did not alter even when paying patients were admitted. Of late, however, it has been realized what demands an extensive clinical service in hospital can make, and there is a tendency to pay whole-time salaries to the chiefs of these services with permission to continue a limited private consulting practice outside the hours of duty at the hospital. Hospital affiliation is a *sine qua non* for the surgeon, and to a large extent for the physician. In large cities in order to maintain a proper standard of organization, hospital staffs are not allowed to exceed certain quotas, so that a high proportion of physicians have no hospital appointments. In smaller communities hospitals give staff privileges to all reputable physicians and surgeons in their area.

The facts and figures in this compilation will have no direct interest for hospital administrators in this country, but much else in the American experience will be found suggestive and stimulating. It is an authoritative and most painstaking work.

Mr. FRANCIS MITCHELL HEGGS has now produced a third edition of *The M.B. B.S. Facts*, being a collection of papers set at the London M.B. B.S. examination for the years 1932–45, classified and arranged under convenient headings. In classifying the questions unnecessary minor subdivisions are avoided by the use of general headings. This booklet is published by J. and A. Churchill at 8s. 6d.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Pye's Surgical Handicraft Edited by Hamilton Bailey, F.R.C.S. 14th ed. (Pp. 668, 25s.) London: Simpkin Marshall, 1947.

A large number of illustrations have been added to this well known manual.

Traité d'Hygiène Vols. 1 and 2. By A. Rochaix, P. Sedallian and R. Sohier. (Pp. 1,098 and 1,898, 2,800 francs for 2 vols.) Paris: Masson, 1946.

Intended to be a comprehensive account of the problems of hygiene in cities, factories, hospitals, schools, etc.

Miracle Drug By D. Masters. (Pp. 191, 10s. 6d.) London: Eyre and Spottiswoode, 1946.

A popular account of the discovery, development and uses of penicillin, illustrated.

Oral Diagnosis and Treatment By S. C. Miller, D.D.S., F.A.C.D., et al. 2nd ed. (Pp. 903, 50s.) London: H. K. Lewis, 1946.

This edition includes new material on penicillin, x-ray diagnosis, oral bacteriology, and extra oral fixation of mandibular fractures.

Belsen Uncovered By D. Sington. (Pp. 207, 8s. 6d.) London: Duckworth, 1946.

A description of Belsen and its inmates by one who was the first British officer to enter the camp on its liberation and the last to leave.

After-Treatment By H. J. B. Atkins, D.M., M.Ch., F.R.C.S. Third edition. (Pp. 328, 18s.) Oxford: Blackwell Scientific Publications, 1946.

This guide to general practitioners, house officers, sisters and dressers contains new material on penicillin and gastric suction.

Les Gliomes Infiltrés du Tronc Cérébral By G. Guillaum, I. Bertrand, and J. Gruner. (Pp. 286, 450 francs.) Paris: Masson, 1945.

After a historical introduction there is a discussion, with many illustrations, of brain stem tumours characterized by absence of raised intracranial pressure and rapid development.

Currents in Biochemical Research By various contributors. Edited by D. E. Green. (Pp. 486, \$5.00.) New York: Interscience Publishers, 1946.

A collection of papers on biochemistry in relation to medicine, agriculture and social problems.

Chemistry of Vitamins and Hormones By S. Rangaswami, M.A., Ph.D., and T. R. Seshadri, M.A., Ph.D. (Pp. 329, Rs. 7.80.) Waltair, South India: Andhra University, 1946.

A short account of the chemical composition and synthesis of vitamins and hormones.

Research and Regional Welfare Edited by R. E. Coker. (Pp. 229, 18s. 6d.) Chapel Hill: University of North Carolina Press, 1946.

A collection of papers presented at a conference on research at the University of North Carolina in 1945. Subjects included are nutrition, research and industry, fisheries, and agriculture.

The Normal Encephalogram By L. M. Davidoff, M.D., and C. C. Dyke, M.D. Second edition. (Pp. 232, 27s. 6d.) London: Henry Kimpton, 1946.

An account of the technique of encephalography and the information obtainable therefrom. Many illustrations.

Studies in Science Edited by W. C. Coker. (Pp. 375, 18s. 6d.) Chapel Hill: University of North Carolina Press, 1946.

Includes papers on penicillin, quinine, regeneration of lymphatic channels following ablation of lymph nodes, parathyroid cysts, and blood volume changes following acute haemorrhage.

1946 Year Book of General Therapeutics Edited by O. W. Behea, Ph.D., M.D., F.A.C.P. (Pp. 443, 21s.) Chicago: The Year Book Publishers, 1947.

Contains chapters on the new sulphonamides, penicillin, streptomycin, influenza virus vaccine, folic acid, and 'benadryl'.

CONTROL AND TREATMENT OF DIPHTHERIA

Diphtheria is an infection of rather insidious onset, characterized by local membrane formation and generalized toxæmia. The clinical disease affects only 5-10% of an unimmunized community among whom the infection is endemic, and deaths or serious sequelæ are rare in patients treated with antitoxin within twenty-four hours of onset. If, therefore, the infection always began acutely with characteristic symptoms enabling early diagnosis and prompt treatment diphtheria would have no terrors for layman or doctor, and large-scale artificial immunization would not be needed. As it is, delay in diagnosis allows the powerful diphtheritic toxin to damage heart muscle and other susceptible tissues before the National Immunization Campaign was started in 1940 this infection caused between 2,000 and 3,000 deaths yearly, and the hospital treatment of 50,000-60,000 affected patients cost over one million pounds. To-day between 50 and 60% of all children aged 1-15 years have been inoculated with diphtheria prophylactic, and the incidence of diphtheria has fallen steadily each year since 1941: the notifications (corrected) are now about one-third of those of pre-war years, and the provisional number of deaths (excluding non-civilians) in 1946 was 444. That immunization has been the main factor in this decline is indicated by the findings that during the years 1942-4 four out of five cases of diphtheria and twenty-nine out of thirty deaths were in unimmunized patients, though the total numbers of immunized and unimmunized children during that period were approximately equal.

These data give no grounds for complacency, nearly one-half of our children remain unimmunized, and every year some 600,000 infants reach their first birthday and require immunization. Furthermore, a baby once inoculated is not thereby made immune to diphtheria for life. In recent years there have been many recorded instances of diphtheria in "immunized" children. The objective in diphtheria immunization must be not only to inoculate 80% or more of our children but to maintain in their blood a level of antitoxic immunity sufficient to reduce to a minimum the risk of diphtheritic infection. The number of queries in our "Any Questions?" column shows that diphtheria immunization still has many puzzling features for both practitioner and medical officer of health. A review of the present position seems apposite.

Diphtheria can occur in inoculated persons for one or more of a number of reasons. In immunization with alum precipitated toxoid (A.P.T.) the antitoxic titre reaches its maximum about eight weeks after the second injection and,

then slowly declines, so that a year later there may be a Schick-reversion rate of 2-8% and in two to five years the Schick-positive rate may be 10-20%. In other words one out of every five inoculated children may again be susceptible to diphtheria a few years after the first course of immunization. If the child had its first course at the age of one year it may contract the infection when it becomes exposed to risk at school or nursery-school. A boosting dose of 0.2 ml A.P.T., which will raise the antitoxin titre to a higher level than ever before, should therefore be given as soon as the child begins to mix with other children, and this boosting dose may be repeated five years later. Among older children receiving their first or second boosting dose toxoid antitoxin floccules (T.A.F.) is the prophylactic of choice, since with it there is less likelihood of reactions.

Another cause of diphtheria in immunized persons is the local invasiveness of the *gravis* and *intermedius* types of *C. diphtheriae*, which allows them to produce a throat lesion—diphtheritic tonsillitis—even in the presence of some antitoxic immunity. This is the probable explanation of the outbreak among older girls in a day-school reported in our present issue by Dr James Fanning. Infection spread although 94% of the girls gave a history of immunization and the Schick-positive rate was only 20% but it is noteworthy that the severe infections occurred among girls who were Schick-positive, or had not been previously immunized, or, if so, had been inoculated more than five years earlier. Too much reliance must not be placed on the Schick test as a measure of resistance to infection since negative Schick reactions have been found in persons with as little antitoxin as 1/100-1/500 unit per ml; it is estimated that the protective level is around 1/30 unit. As a rule infection with *gravis* or *intermedius* strains in Schick-negative or previously immunized persons is atypical, being characterized by follicular exudate rather than membrane, an acute inflammatory reaction with local oedema, and a higher temperature than is usual with diphtheria. It is therefore sound practice to have a bacteriological examination made of any case of follicular tonsillitis, because an atypical diphtheria of this kind, though it may not require antitoxin, is likely to spread infection in school or at home if allowed to go undetected. If an outbreak occurs in a highly immunized semi-closed community probably the best procedure is to carry out large-scale swabbing of contacts, isolate carriers, and give everyone a boosting dose of T.A.F.

A third possible explanation of diphtheria in the inoculated is the use of a poor prophylactic reagent. Thus it has been found that after two doses of T.A.F. the Schick relapse rate may be as high as 30% in two years' time.¹ Considerable variation may occur with different preparations even of A.P.T., though a minimal standard of antigenic potency as measured by the response in the guinea-pig is accepted by manufacturers in this country. Holt, using a purified toxoid precipitated with pure aluminium phosphate, has attempted to eliminate the variables, and it may happen that this new reagent—diphtheria toxoid

¹ Croft J M, Spooner E T C, Marmion M B, and Booth W G, *Monthly Bull. Min. Hlth & P.H.L.S.* 1945 4 175.
² Holt, L B 1947 1 282.

aluminium phosphate precipitated—will in time replace the more variable A P T. The alum-precipitated prophylactics given in adequate doses of 0.2 to 0.3 ml. are good immunizing agents because they create a depot and thus ensure an effective sensitization of the antibody mechanism so that when a second dose is given one month or even one year later there is rapid formation of antitoxin. However, although there is nowadays an increasing tendency to begin diphtheria immunization earlier than one year of age—because cases and deaths do occur in infancy—we still do not know how good is the antibody response which the rather immature tissues of the infant can make to an antigenic stimulus. In any event, if immunization of the older children is maintained at a high level the risk of the baby's being exposed to infection will be small.

In the treatment of diphtheria with antitoxin the most important point is to give it as early as possible and by the most effective route, for antitoxin is more prophylactic than curative and cannot undo damage that has already been done by the toxin. There is a steady rise in deaths from diphtheria with each day's delay in treatment. Practitioners are still far too reluctant to give a dose of antitoxin to the 'early doubtful case', with the present refined antiserum a dose of 8,000 units, sufficient for the early case, is contained in 1–2 ml., and the risk of reactions is minimal. For the toxicæmic case about half the dose should be given intravenously, because absorption after intramuscular injection is relatively slow. No antibiotic can replace antitoxin in the treatment of diphtheria, but, combined with specific therapy, penicillin either sucked from pastilles or preferably given systemically may help to eliminate the organism from the throat more quickly than usually happens. For the mild or early case or for diphtheritic tonsillitis in the immunized penicillin may be used alone, though only the experienced physician will want to take the risk of omitting antitoxin from the treatment of a disease which is essentially a toxicæmic infection.

A FULFILLED MANDATE

UNRRA has passed into history with a record of accomplishment in public health on an unprecedented scale and with results of vital importance for the world. The Health Division came into existence at the end of 1943, so that field operations of any magnitude have covered a period of little more than two years and in many countries much less. During that short time medical and sanitary supplies have been provided in great abundance, national health departments resuscitated, epidemics prevented or arrested and the aided countries started on the way to recovery. The threat of famine and disease, the inevitable progeny of war and hardly less dreadful than war itself, menaced the devastated Continent. The wars of former times, relatively local conflicts, were yet followed by pestilences which often lasted longer and took heavier toll of life than the fighting itself: the uncontrolled after-effects of a world wide war baffle the imagination. Fortunately there were two restraining factors and UNRRA was the minister of both of these. One was the growing sense of international responsibility fostered by the

instincts of self-preservation and compassion, the other was the recent progress in medicine and public health—for example, the introduction of DDT.

The Health Division has operated in a dozen or more countries of Europe, carried out a vast programme of relief in China, and dispatched a mission to Ethiopia for the development of indigenous health services there. Assistance in the provision of medical supplies and organization of public health was at first limited to the invaded allied countries that had been seriously damaged and lacked foreign exchange; later it was extended to Italy and Austria, and to some extent to Hungary. In Germany UNRRA has had no responsibility for German nationals, its main function has been the care of displaced persons. Food, of course, was the first requirement, and UNRRA ensured for the most impoverished countries which were unable to compete with those having foreign exchange assets some share in the supplies available from the great producing lands. Serious under-nourishment still persists in several European countries but without UNRRA the situation would have been catastrophic.

The greatest achievement of the Health Division was the prevention of epidemic disease. During the four years of the first world war and the four years after it influenza, typhus, relapsing fever, malaria, smallpox, typhoid, and the dysenteries caused more loss of life than the war itself. An epidemic of louse-borne typhus in half a dozen countries outlasted the earlier war for six years. At that time no international anti-epidemic action was taken except for an effort by the League of Nations to stop the tide in Poland. To-day typhus is only sporadic, cholera has never appeared west of India, smallpox is rare in Europe, typhoid fever, after a serious epidemic in Poland and Germany, is once again under control, diphtheria, except in certain parts of Germany, shows a marked reduction in incidence, plague has gained no foothold, though at one time the occurrence of a number of cases on the Mediterranean seaboard caused anxiety. As for influenza, although the winter waves have come and gone, there has been no pandemic like that of 1918–19. However, UNRRA can take no credit for this providential deliverance, for had a pandemic threatened there would have been neither sufficient vaccines nor the means of bringing them to the masses in peril. The *Epidemiological Information Bulletin* in its final number issued by UNRRA from Washington, is scarcely exaggerating, nevertheless, when it declares that public health and medicine come out of this war as the only victors.

Re-establishing the exchange and co-ordination of epidemiological information has enabled danger-spots to be discovered and concentrated action to be taken. Except for the Pan-American Sanitary Bureau, this world-wide network was disrupted during the war, the League of Nations service remained at Geneva, but its communications were strictly limited. UNRRA took over the Health Research Unit of the League of Nations at Washington, expanded it into an Epidemiological Information Service, and set up a parallel service in London in the European Regional Office. It also opened by means of its China Mission, through the helpful agency of the China

National Health Department a service of information about cholera and plague in that country. In addition the British Government last year opened the Far Eastern Bureau. In the early part of 1945 UNRRA took over the duties imposed by the International Sanitary Conventions of 1944 governing the precautions against the spread of epidemic disease, the one for maritime and the other for aerial navigation, and became the receiving and transmitting agency of all notifications from the signatory Governments.

Some day, it is to be hoped, a historian will tell in full the story of this first exciting and formidable chapter of relief and rehabilitation. The programme of medical supplies reads like a fairy tale of shipments—over a million pounds of sulphonamide drugs, over 800,000 million units of penicillin, between 600 and 700 million units of insulin, over 1,200,000 pounds of aspirin, over 5,000 million units of diphtheria antitoxin and over 6 million millilitres of the toxoid. As for DDT the consignments are measurable by the millions of pounds of the powder and the millions of gallons of the solution. Almost all the displaced persons in the camps in Germany have been immunized against typhus, typhoid fever, and smallpox. Within seven months of the entering of Albania, hospital equipment, drugs and dressings sufficient for 30,000 people were delivered and enough DDT powder to protect the whole population for a year. In Greece where tuberculosis was a difficult problem, about twenty dispensaries, started by UNRRA tuberculosis teams are now in operation. In Yugoslavia typhus and malaria controls have been set up, clinical and dietary surveys carried out, and supplies and equipment provided. In the Balkans and Italy the results of an intensive anti-malaria campaign have been spectacular. Equipment including aeroplanes specially devised for aerial spraying with DDT, has been handed over to the Governments or to the World Health Organization. Country after country has received not merely largesse but consultation, collaboration, and training from selected health experts. UNRRA enlisted a professional staff of several hundreds—more than two hundred from the United Kingdom alone. Between 500 and 600 physicians were assigned to the assembly centres for displaced persons or to hospitals and clinics for the general population and large numbers of public health personnel were employed in an administrative or advisory capacity and in field work in their specialties. Dr Andrew Topping, Director, Medical Division, has gratefully acknowledged the help of local authorities in releasing public health officers for this work notwithstanding the pressure on their own departments.

The Health Division has now handed over the administration of its functions apart from those relating to the health of displaced persons to the Interim Commission of the World Health Organization, with its headquarters at New York City and its Epidemiological Information Service at Geneva. The Commission will also assume the functions of the International Office of Public Health, which worked from Paris until it was disrupted by the German occupation. The International Refugee Organization will eventually take over the care of displaced persons until they are ready for UNRRA medical,

dental, and nursing staff will continue to be responsible and it is expected that the majority will be absorbed into the new organization. Other transferred activities will be the training of health personnel by means of fellowships and teaching abroad, advice and assistance in the control of tuberculosis and malaria, and the sending of expert missions to countries with special needs. The medical and administrative teams in Britain and the United States of America hand over their mandate with satisfaction and the expectation of harvests to come. There has been a great and humane achievement.

A NEW TREATMENT FOR POST-OPERATIVE PULMONARY ATELECTASIS

Increasing knowledge of the pathogenesis of post-operative pulmonary complications and of methods of prophylaxis against them has led to *diminution in their frequency*, but it will always be necessary to perform operations on unfavourable subjects and at unfavourable times, and hence post-operative atelectasis may be expected to continue to present a therapeutic problem. Grandstaff¹ has recently reviewed the respiratory complications in a series of 2,704 operations at the Kansas City General Hospital. Some of his figures are surprising, for instance, in a series of 19 patients anaesthetized with nitrous oxide-ether sequence there were 10 cases of post-operative pneumonia, with 2 deaths. The mortality from pneumonia in 100 cases anaesthetized with cyclopropane-ether was 1%, and in 102 receiving spinal anaesthesia and nitrous oxide it was 3%. The total incidence of respiratory complications in the whole series was 2.6%, and of pneumonia 1.8%, and of the 51 patients with pneumonia 24 died. Grandstaff points out that high oxygen concentrations in inhalational anaesthesia, as are employed with cyclopropane, favour the occurrence of atelectasis, and it is his practice to give nitrous oxide during the last few minutes of cyclopropane anaesthesia to minimize this effect. He claims dramatic results in post-operative atelectasis, before pneumonic changes have occurred, from the application of 5% to 10% cocaine to the pharynx and pyriform sinuses as if in preparation for bronchoscopy. He states that the effect is not produced only by the stimulation of cough, because the same results were not obtained by merely applying a swab moistened with saline solution to the throat. He presents reports of five cases in which a post-operative atelectasis cleared up dramatically after this procedure had been tried, and states that since he introduced this method it has not been necessary to resort to other procedures for the relief of the atelectasis. It is clear that the evaluation of a procedure which inevitably produces severe coughing as a treatment for atelectasis is difficult. Grandstaff suggests that cocaineization of the throat acts by producing a reflex relaxation of the bronchial musculature, and although this explanation may seem a little far-fetched it is at least feasible. The method seems to be worth a trial.

POISONING BY IRON SALTS

Copper and manganese belong to the group of trace elements without which plants do not flourish but which are deleterious in excess. The same probably applies to animals, but on a normal diet and with normal absorption there is no question of either deficiency or excess. The position is very similar for the much larger amount of iron required apart from the deficiency which may arise from

loss of blood. It is now the custom to add copper and manganese to the preparations of iron needed when there is evidence of iron-deficiency and this seems to make medication with iron more efficient. However preparations of iron are to a certain extent toxic and the question arises whether such preparations with small quantities of copper and manganese, though more efficient may not at the same time be more poisonous in excessive doses or in those who are sensitive.

Dr Gilbert Forbes has seized the opportunity presented by those unfortunate accidents which arise from the experimental attitude of young children to materials they can swallow. He describes (p. 367) how two children aged respectively 3 years and 3 months and 1 year swallowed a preparation consisting of ferrous sulphate with copper sulphate and manganous sulphate. The elder child swallowed about 50 and the younger about 30 tablets each tablet contained 1/75 gr (0.87 mg) of the copper and of the manganous sulphate for each grain of ferrous sulphate. Both died. In neither case was there evidence of excessive absorption of copper or manganese. The elder boy showed some jaundice, and in both there was evidence of necrosis of the liver and of other organs. From experimental work on animals Forbes concludes that the toxic agent is essentially ferrous sulphate and that the copper and manganese are in too small a proportion to contribute to the toxicity of the relatively enormous doses taken.

It is well known that young children are much more vulnerable to certain drugs and poisons than are adults and that they absorb many substances more freely. However Forbes's results do suggest that overdosing with iron preparations is undesirable especially in individuals who are sensitive. Among metallic poisons those that are relatively easily absorbed are regarded as the more poisonous, but, granted that the metal is absorbed, there appears to be no essential difference in their toxicity except in the case of arsenic. 'BAL' (British anti-lewisite) was introduced as an antidote for arsenical war gases and was later applied to the treatment of arsenic-poisoning.¹ It has since been used successfully by intramuscular injection in acute mercurial poisoning. There is no obvious reason why 'BAL' should not be useful in other metallic poisonings particularly where the metal has a characteristic sulphide

favour of both of them. In combination with sulphonamides there is at least an additive if not a synergic effect. Inhibition of growth is achieved by concentrations of urea or urethane on the one hand, and sulphonamides on the other which when acting alone are ineffective. There is also some evidence that these two substances counteract the anti-sulphonamide effect of *p*-aminobenzoic acid, but the concentrations required are relatively so great and the effect so transient that this seems unlikely to be a factor in any success which the combination may have as an antiseptic. Weinstein and McDonald go further and suggest that urea and particularly urethane if used in sufficient concentration have so pronounced an independent action on bacteria that the addition of a sulphonamide may not have much value for the purpose of wound treatment. They propose that a mixture of urethane and penicillin should be used for treating mixed infections in wounds. Urethane serves to suppress coliforms which are not only resistant to penicillin but may destroy it, the penicillin deals with staphylococci, which are more resistant to urethane. That this combination will suppress the growth of both organisms together they have proved under *in vitro* conditions. Whether the liberal application of urethane may have any harmful effect is not discussed. Apart from this possibility the method seems worthy of a trial.

FELLOWSHIPS IN PLASTIC SURGERY

Sir Simon Marks has established three fellowships per year in plastic surgery, each to the value of £740 per year for two years tenable at Queen Victoria Hospital, East Grinstead Sussex. These Fellowships will be known as the "Simon and Matilda Marks Fellowships in Plastic Surgery."

This magnificent gift is undoubtedly a great contribution to surgery and will be warmly appreciated by the medical profession. The Queen Victoria Hospital East Grinstead has grown remarkably during the war. It has benefited by gifts from Canada, Australia, New Zealand and South Africa with the result that the buildings and equipment are of the most modern type. The recent addition of the American surgical wing, opened by the Queen last year and representing the memorial gift of the British War Relief Society of America went far to make this plastic centre the best in the Empire. Sir Simon's gift will ensure that the facilities at East Grinstead will be used in postgraduate education. He is to be congratulated upon his far-sighted generosity.

UREA AND URETHANE AS ANTISEPTICS

Urea was first applied to wounds chiefly as an aid to cleansing and the dislodgement of sloughs. Later it was combined with sulphonamides, with which, according to some American authors, it has a synergic action. The effect of urea and of urethane, which has been similarly used alone and in combination with sulphonamides has been thoroughly investigated *in vitro* by L. Weinstein and Alec McDonald with a view to explaining discrepancies in earlier findings.

Each of these substances has a direct action on bacteria that of urethane being about four times the more potent. Thus 2% urethane or 8% urea inhibits the growth of most bacteria. Concentrations of 10% and 20% respectively are bactericidal. A remarkable feature of this action is that Gram-negative organisms including so intractable a species as *Pseudomonas* are more susceptible than Gram-positive. The most resistant common species is *Staphylococcus aureus*. The urethane increases the solubility of sulphonamides another effect which has been urged in

"DOCTOR" SIGNS ON CARS

During the war the movement of cars had to be greatly curtailed and a traveller was likely to be stopped and asked by the police whether his journey was really necessary particularly if an air raid was in progress or troops were on the move. In such circumstances the "Doctor" sign on the windscreen afforded valuable protection against unnecessary delays in "doing the round." The need for it now however has vanished with the conditions that once made it a justifiable practice. It has been suggested that the police might relax parking regulations and not bother the owner of a car standing for an hour or more at the kerb but medical men are not entitled to any special immunity from the law. Though to display the sign may be convenient, it may come to be regarded as a form of self-advertisement. It has been suggested that some medical men do so regard it. To avoid any suspicion of this, medical men should discontinue a wartime habit.

Correspondence

First Things First

SIR,—If there are insufficient hospital nurses Mr Bevan's prophecy that we shall soon have the finest medical service in the world is unlikely to be fulfilled. Thousands of hospital beds have been closed down for want of nursing staff, and the remainder are understaffed, giving rise to overwork and more resignations from the nursing service. All reforms are doomed to failure unless suitable accommodation can be provided for nurses. Cannot Mr Bevan persuade his right hand—i.e., the Minister for Housing—that it is essential to help his left hand—i.e., the Minister of Health? Without such help the hospital service of the country is bound to fail. In peacetime women will not agree to live in buildings designed like old fashioned barracks, nor are they prepared to sleep two in a room. Few hospitals to day have sufficient accommodation for nurses in order to start eight-hour shifts, and some have insufficient accommodation even for two shifts. The subject of accommodation is very urgent. The Government has realized that there is an electricity shortage, and it will take two years to build a power station, but it takes four years to train a nurse—I am, etc.,

MALCOLM DONALDSON

Groundnuts in East Africa

SIR,—The leading article on groundnuts in East Africa (March 8, p 301) points out the benefits which the Government scheme bids fair to confer on this country and the African. Too long has it been assumed that vast areas of East Africa are of no value to mankind and fit only to be relegated to big game and the tsetse fly.

The largest block of land selected, and that where operations are to be commenced, lies in the Southern Province of Tanganyika long noted for sleeping-sickness, increasing inroads of the tsetse fly, and the abundance of big game. In 1942 no less than 572 elephants were killed in that province.

Inferences drawn from fly clearances on the west coast, where conditions are dissimilar, will be of little value in Tanganyika. But in S Rhodesia, by the natural means of depriving the fly of its food supply, the Government has already rid nearly 4 million acres of 'fly,' and the clearance of another 2½ million acres is nearing completion. Settlers, with their cattle, are already established on land previously resigned to game and fly. Under the direction of Mr Chorley, the Government entomologist, native hunters have destroyed the game, the 'fly' has been starved out.

In his annual report for 1942 the Provincial Commissioner S Province, Tanganyika, stated that "vermin, in which term are here included elephant, hippopotamus, and other game continue to take great toll of the African's crops." It may be assumed that the business men in charge of the groundnut scheme will not permit the wreckage of their works by these animals. But no benefit will accrue to the African, except possibly those actually employed on the groundnut scheme, if the game (and 'fly') are merely driven away to native occupied land. Only aggravation of the state of affairs reported by the Provincial Commissioner can result from such action. The game must be destroyed, as it has been, with such beneficial results, in S Rhodesia.

All administrative officers undergo anthropological training and, better still, acquire an intimate knowledge of native life and customs in their daily work. There is no need, therefore for the dispatch of 'anthropological experts,' who would only be beginning to understand the local natives by the time that the extra fat was being consumed in this country—I am, etc.,

Arsenical Encephalopathy

SIR,—It was with great interest that I read the article by Drs G Hipps and R Goldberg on arsenical encephalopathy (March 8, p 296).

While serving as a V D specialist in a large V D hospital in Bengal I saw over seventy cases of arsenical encephalopathy

all of them proved post mortem. During this time—August 1943, to June, 1944—many other hospitals in India reported large numbers of cases of arsenical encephalopathy.

The case reported was very typical in its origin with its aura—but we sometimes noticed that the man had complained of slight headache and of feeling unwell after his previous injection. These symptoms were thought to be of great significance. Their case is also typical with its convulsion but we did not notice tongue-biting, and almost always we noticed athetoid movements, which do not seem to have been present in the case reported. The high rise of temperature before the end is also typical and their post mortem findings are just as we always found in India. I quite agree with the authors on the unusual feature of their case. First, the long time interval before the condition developed. All our cases occurred between the second and fifth injection, nearly always after the third. Death was much more rapid in our cases and sometimes occurred twenty-four hours after the first symptoms. Thirdly, in our hospital we had no authentic case of recovery from arsenical encephalopathy. Death occurred in all cases. Our cases were all of early syphilis, no cases occurred in congenital syphilis. The treatment of early syphilis was then 0.3 or 0.45 g NAB with 0.2 g bismuth then 0.6 g NAB after 5 days and then 0.6 g NAB and 0.2 g bismuth weekly. Our treatment of the encephalopathy was very similar to that carried out by Drs Hipps and Goldberg.

Another important feature was that most of the cases were Indians, and I can only remember three cases in Europeans. Furthermore, the Indians were usually Southern Indians, in whom there is often a dietary deficiency in protein, and it was suggested that this could have been a contributory factor—I am, etc.

J M H McMURRAY

London Clinic for Epileptics

SIR,—Many of your readers are interested in one aspect or another of the difficult problem of the epileptic. These unfortunate people often find it hard to secure a place in industry even with the assistance of the DROs at the employment exchanges. A considerable number are known to be drifting about in the community in need of medical advice or of help with their social problems.

In an endeavour to meet this situation a clinic has been established by the London County Council at St John's Hospital St John's Hill, Battersea, on Wednesday afternoons at 2.30. The medical officer in charge is a senior officer seconded from St Ebba's Hospital and an experienced psychiatric social worker is in attendance. The clinic works in close association with the employment exchanges and with the colonies for epileptics, and it is understood that excellent results are being obtained. Doctors in private practice or on hospital or clinic staffs who wish for advice on epileptic patients living in London should make an application to the psychiatric social worker at the hospital—I am etc.

Anaesthetic Apparatus and Cross-infection

SIR,—Writing in 1873 Skinner made the following observations on the use of anaesthetic apparatus:

"There is no one inhaler, my own excepted, where every patient is not made to breathe through the same mouthpiece, tube, and chamber. Sweet Seventeen is made to follow another whose nasal and pulmonary mucous membrane leave alone the cutaneous surroundings of the mouth and nares may be exhalant of all odours but those of purity and innocence."

Reading this recently reminded me of attempts made by the theatre sister to clean the rebreathing bag of our Coxeter Mushin apparatus as she thought it a nasty habit for all the patients to breathe out of this. A search of the literature revealed only one reference to the possibility of cross infection from anaesthetic apparatus, and that did no more than mention the possibility of the soda lime acting as a bacterial filter. I therefore thought it worth while to record some actual experiments performed on our apparatus. Already a swab had been sent to the laboratory from the inside of the breathing bag

This was returned. The swab contained a green mould Culture heavy growth of haemolytic *Bact coli*

It is my practice not to switch on the soda-lime absorber for the first few minutes of an induction so I next took the following swabs (1) from the expiratory valve before absorption and ether sparse growth *Bact coli* (2) from the inspiratory valve before absorption and ether one mycelial colony only, (3) from the expiratory valve after a half-hour's absorption and ether sterile, (4) from the inspiratory valve after a half-hour's absorption and ether sterile. This seemed reassuring so I used the apparatus for a whole morning's work—the last two cases being short gas-and-oxygen anaesthetics in which I used the Mushin apparatus without absorption and again I took swabs from the valves and absorber ends of the corrugated tubing. These results were (1) expiratory valve a few discrete colonies of pneumococci (2) inspiratory valve sterile after 24 hours culture. I may add that the face-pieces are immersed in biniodide solution between cases but the corrugated tubing is merely hung up when not in use.

It seems safe therefore to deduce that there is no danger of cross-infection from bacteria in a modern anaesthetic apparatus using soda-lime absorption and it even seems safe without the use of soda lime. There is still the possibility of virus cross infection and this is a matter which is perhaps worthy of investigation—I am, etc

Psycho-analysis

SIR—In your excellent account in your obituary column (March 8, p 316) of Pierre Janet's record you state that Freud's psychoanalysis produced better results than those of Janet. Is there absolute proof of this assumption? Janet's work, as you so aptly described, was on the lines of hypnotic suggestion, whereas Freud by his psychoanalysis reduced the complex regressions apparently by his reduction of abreaction. In the last generation of such giants in hypnotic treatment alone, where no psychoanalysis was used but only hypnosis how do you account for the remarkable results attained at the Nancy School by Liebault and Henri Bernheim also Wetterstrand of Stockholm who used hypnosis alone? Does it not prove that exalted suggestibility alone may reach the deep centres? Bleedings were produced rapid pulses were slowed down and in Wetterstrand's work in a case of paroxysmal tachycardia with the pulse running at nearly 200 beats per minute sphygmographic tracings showed the beats under hypnotic suggestion alone slowing down to 80 per minute. Bernheim produced blistering under hypnotic suggestion and Liebault practised among the poor at Nancy for 30 years using hypnotic suggestion alone and his results lasted and were excellent. This is all a true and strange paradox, and it would be interesting to have your comments on this where no Freudian methods were used—I am, etc

JOHN R O BRIEN

World Food Council

SIR—With reference to the opening statement in the annotation on the above (Feb 8, p 228) it has to be emphasized that questions arise at once where the food ought to be grown and whether it is necessary for poor nations to increase their purchasing power in order to buy their food from abroad. Advocated by high-powered emotional appeal regarding starving nations the "World Food Board" plan aimed at stabilizing prices by means of buffer stocks and at disposing profitably for the producers, of unmarketable surpluses.

To deal with the last point first in the plan the starving nations were in reality to be used merely as dumps for excess food after it had been paid for by a third party, obviously to the great benefit of privileged countries and persons—the professional producers for sale of food, a very small part indeed of the world's population. The aid of 'starving' nations, with a population mainly of non-industrialized peasants and abundant cultivable land could, however, be enlisted in their

own interest to solve their underfeeding problem for good and all by their being educated and even constrained to grow the food for their own food (more likely to be of a suitable nature) on the spot—a different proposal of course from that of using large scale loans as a means of developing backward countries—backed up to the hilt moreover by the results obtained by amateur plot holders during the war.

For the professional food producing countries the solution of their long term problem lies of course in adapting supply to demand and in diversification of industries. Buffer stock measures that textbook commonplace and the present case cure all are a purely palliative make-shift contrivance applicable only internationally for the temporary alleviation of the effects of depressions. Their use internationally is impossible because consumers' interests are diametrically opposed to those of producers. They are moreover an example—a hidden one—of that universally condemned expedient the export subsidy the international variety of which would add insult to injury by requiring foreign industrial consumers to provide at considerable expense and loss of bargaining power the major part of the funds for the subsidy. Buffer stock schemes moreover are liable to other disabilities. Enormous expenditure would be involved in carrying them out. Where a commodity is produced at home and abroad the existence of tariffs to protect domestic production would prevent the establishment of a world food price the essential basis for their formation. Stocks would deteriorate on storage and finally, and worst of all because of further food prices to the producer there would be overproduction of food with unmarketable surpluses—a situation incapable of being met by production-control measures in view of the inelasticity of supply and demand. We are not dealing here with philanthropy and on a purely economic basis the building up of reserves to meet possible famine conditions ought to be the obligation solely of those nations subject to such hazards.

The development by Sir John Boyd Orr of the World Food Board plan from the suggestion by Mr S M Bruce in 1935 of a marriage between nutrition and agriculture and the composition of the Preparatory Commission to inquire into its soundness could be discussed in some detail with considerable advantage. Further remarks however will be confined to observations on a recent occurrence which in many respects supplies an up-to-date summary of the situation. In the House of Commons on Feb 6 Mr H Wilson MP reported on and supported the findings of the Preparatory Commission. Mr Richard Law MP suggested that both Mr Wilson's speech and the report buried Orr's proposal of a World Food Board whereupon Mr Wilson interrupted to say that Sir John Boyd Orr was highly delighted with the report. The obvious comment is that somebody has queer ideas of relevancy and refutation in a reply and that somebody else appears to be remarkably easy to please and to be liable to self-persecution as the quotation from the *Observer* (see *h M J* Feb 8 p 228) also demonstrates—I am etc

Aberdeen

J P MCGOWAN

Use of Penicillin Pastilles

SIR—Dr T H Manners Kerfoot states (Feb 1 p 197) that stomatitis after oral penicillin may be due either to the penicillin or the sucrose base. He argues that as the sucrose base is used in other pastilles not containing penicillin without causing stomatitis the penicillin must be the cause.

There is an alternative explanation that both penicillin and sucrose base are required to produce stomatitis. I believe this to be the true one for the following reasons. (1) As Dr Alexander MacGregor (p 197) points out in the original work on penicillin pastilles we treated over a thousand patients without causing stomatitis the base in this case being soft and viscous. (2) If sufficient penicillin is given by the systemic route it is secreted in the saliva producing the same changes in flora of the mouth as are obtained by local treatment. These patients do not develop stomatitis. It would appear therefore that penicillin alone or penicillin in a soft base does not cause stomatitis. If however patients having systemic penicillin at the rate of approximately one million units a day are given boiled sweets to suck they develop the condition.

The clinical evidence supports this suggestion, penicillin stomatitis starting in the areas receiving the most trauma, namely the tip and sides of the tongue, even in the later stages the more protected areas tending to escape. Though the pastilles and the trochisci both contain sucrose, the trochisci contain the greater quantity. It may be that continuous sucking of such a base alone would produce stomatitis, the importance of the penicillin being merely that more intensive treatment is prescribed when penicillin is an ingredient than when it is not. While Dr Kerfoot's observations suggest that this is improbable with the lozenges that he prepares it is conceivable that the continuous abrasive action of sucrose crystals on the buccal mucosa, supplemented perhaps by the osmotic effect of a hypertonic solution may be sufficient to cause stomatitis in the absence of penicillin. Observations on the point are desirable.

Quite apart from the relationship between the trochiscus and stomatitis there are other grounds for criticism. Dr MacGregor stressed the importance of a viscous base if the maximum effect is to be obtained on the tonsils, quoting the references for his opinion. This being so I will merely state that I am in complete agreement with him. The trochiscus is unsuitable for use in plastic surgery of the mouth because it is so hard that the patient will not tolerate it, and even if he can be persuaded to maintain it in a less sensitive part of his mouth the base accumulates in intra-oral wounds and has to be removed manually.

In conclusion I would stress that I consider the trochiscus penicillin highly unsatisfactory for the reasons stated, and hope that the manufacturing companies will soon devise a more suitable base. Until then, I believe the original pastille devised by Dr MacGregor and myself to be the most satisfactory in spite of its limited keeping properties—I am, etc.,

London WC1

DAVID A LONG

Delayed Reaction to Penicillin

SIR—The recent article by Dr A I Suchecki (Dec 21, 1946, p 938) on allergic reactions to penicillin prompts me to record a case where the reaction was unusually delayed.

CASE REPORT

At Forest Isolation Hospital, Mansfield, a girl of five years, suffering from bronchopneumonia following whooping cough received 400 000 units of penicillin in four-hourly doses from Dec 15-19. The penicillin used was an ordinary commercial brand in aqueous solution, injected intramuscularly. Rapid improvement was followed by a slight relapse ten days later, and sulphathiazole 8 g was given orally from Dec 30 to Jan 4.

On Jan 27—i.e., 39 days after cessation of penicillin and 23 days after cessation of sulphathiazole—she developed a raised, pink, blotchy rash, generalized in distribution but most marked over the sites of penicillin injections, oedema, especially of the hands and eyelids, pruritus of moderate degree, pyrexia of 101° – 103° F (38.3° – 39.4° C) and considerable bronchospasm which was temporarily relieved by adrenaline. There was no arthralgia, no hydrarthrosis, no lymphadenopathy, and no jaundice, and the urine was normal in all respects. The features which persisted longest were the oedema (which subsided on Feb 1) and the rash (which disappeared on Jan 31). On the neck the fading of the utricular eruption coincided with the appearance of a number of petechiae.

The most delayed penicillin reaction previously known to me was Dr J N Turnbull's case (Jan 18 p 111), where the reaction occurred 35 days after cessation of parenteral treatment. A delay of 39 days before the appearance of an allergic reaction is certainly most unusual yet the features were unlike those of a sulphonamide drug rash and were completely in line with those of penicillin reactions as described by Suchecki and others—I am, etc.,

I A G MACQUEEN

Endocrines in Gynaecology

SIR—The fact that the action of hormones depends not only on the hormones themselves but also on the mode of reaction to them of the target cells is well known in endocrine biology, and is bound up with the general conception of "biological field"—a conception which we owe to the brilliant work of J Needham and C Waddington. Albright coined the

characteristic expression 'Seabright bantam syndrome'. T male Seabright has female feathering, which is attributed to any predominance of female hormone in the bird but to the special reaction of its feathers to male hormone. This conception enables us to understand much of the physiopathology of endocrine diseases.

Mr Aleck Bourne (Jan 18, p 79) has rightly stressed the importance of this biological principle in practice. Endocrine diseases are not diseases of one of the six classical glands of internal secretion but disturbances in the balance of a whole system of constitutional or metabolic regulation composed of the genes, endocrines, neurovegetative system, psycho-associational cortex, certain environmental factors, and the reactivity of the cells—the "competence" of the biologists. Thus endocrinotherapy is not the sole method of treatment of endocrine diseases. On the contrary, its one-sided application may do harm by upsetting the balance of the system of constitutional regulation as shown by the bad effects of an exclusively endocrine treatment in certain eunuchoidisms in the young and by the disasters of attempts at rejuvenation with testicular organotherapy.

At the Annual Meeting of the BMA at Oxford in 1936 I opened a discussion on physical methods in endocrinotherapy, in which I stressed the importance of physical medicine in modifying the balance of the system of constitutional regulation and thus its superiority, in certain endocrine diseases, over organotherapy. In endocrine as in all other diseases we deal with the complete psycho-physical personality. It is curious that psychiatry and endocrinology, the two branches of medicine which have contributed to our modern concept of total personality in disease, seem to revert to the comfortable one-sidedness which they have been fighting; psychiatrists stress unduly the psychological factors at the expense of the organic factors while endocrinologists seem to dwell exclusively on the hormones with which we have been flooded—I am, etc.

A P CAWADIAS

Endocrine Receptors in Relation to Cancer

SIR—No doubt the idea that an endocrine stimulus or impulse must be received as well as transmitted has occurred to many, though I agree with Mr Aleck Bourne (Jan 18, p 79) that it has not been given the prominence which Mr Bourne rightly, I think, considers it should receive. The idea, however, was the main point of a paper entitled "A Theory of Cancer" published in the *Lancet* 1920 2, 1,298. It did not attract any particular attention as far as I know and I only remember it because I wrote it and because I have never ceased to think of endocrine glands in general as structures which not only transmit a particular kind of energy but whose effectiveness depends on the proper reception of the message transmitted. I suggested, in fact, that sensitivity to hormone messages was a necessary function of every normal cell of every tissue and I endeavoured to trace the sequence of events that must occur in a group of cells in which this function was being imperfectly carried out as the result of a failure to cope with an excessive demand on the regenerative capacity of those cells. I was not thinking of special hormones but of what I called the "co-ordinating hormone" a hypothetical hormone whose existence it seemed to me to be a logical necessity to assume, as in no other way could the harmony of growth and function of all normal tissues be explained.

I venture to recall these points now as a comment on Mr Bourne's paper because I thought that the idea of receptors (or, as I called it, cell sensitivity) could be applied to Dr A Paine's then recently published paper (*Lancet* 1920 2 692) on the origin of cancer. Dr Paine's views may be epitomized in the following quotation from his paper: "We have thus traced cancer to its source, it springs from a degenerate cell, a cell that has in some manner been damaged or injured, and from such a cell all cancer cells are descended." In my paper I attempted to show that cells so degenerated gradually failed in all their functions, both special and general, I tried to make the point that this failure must include the failure to respond to the message of the co-ordinating hormone and that failure in this function must inevitably result in cancer—I am, etc.,

Leicester

T C CLARE

National Health Service

SIR—Having read no constructive criticism of the National Health Service I offer the following. At the plebiscite I voted No, because I am against any form of compulsion, unless it be in war or for the maintenance of peace, law and order, or in cases of unsound mind. Under the present Act of Social Security and National Health everyone is compelled to contribute a certain weekly sum, for which in return he will receive certain benefits. This should in my opinion, be voluntary. The insurance company to whom premiums are paid should be a matter of individual choice. State or private.

A health service should be organized by the State for the benefit of those who pay their premiums and for those who are unable to pay at all. Consulting rooms, hospitals etc. should be provided and staffed. Vacancies on these staffs, some whole time, some part-time, should be filled by advertisement in the usual manner. Pay and conditions being good, there would be ample people to fill them. In addition these State-controlled hospitals would offer accommodation for all with three classes of luxury: those not in the State insurance scheme paying the usual fees and anyone wishing more luxurious accommodation paying the excess—the treatment in every hospital being carried out by its own staff. Private hospitals and nursing homes would remain as at present as also would the public health services.

Medical teaching would be provided at the State hospitals and in the consulting rooms, in collaboration with the universities and colleges. Each doctor would be able to choose to work in private practice or part- or whole-time in some branch of the State Service.

I cannot in such a short space give a scheme in complete detail but if it is worth doing it should not be too difficult. There is still time to start again and to produce complete medical facilities for all, based on the principles of freedom, and giving everyone the opportunity of being responsible personally for the care and future of himself and his family. It is only by giving such responsibility to the individual that the moral fibre of the country can be saved.—I am etc.

Southsea, Hants.

J. T. FURNIVALL

Two Negotiating Committees, Past and Present

SIR,—The strongest impression I took away with me from the recent Special Representative Meeting was the lack of confidence shown in the Negotiating Committee. One resolution which was carried asked them to resign; others tried to impose terms of reference upon the new Negotiating Committee, and many more asked the new committee to report back frequently. What is wrong with the old and new Negotiating Committees? It is not the individual members that are at fault, it is the constitutional set-up that makes it unsuitable to carry out the functions invested upon it.

The B.M.A. has been recognized as the only body capable of negotiating on behalf of all shades of medical opinion. It represents the Royal Colleges, the consultants, medical officers of health, the Medical Women's Federation and the general practitioners. Therefore the first Negotiating Committee, which had to discuss mainly the fundamental principles of the Act, should have represented the B.M.A. only and no other body. The committee would then have been bound to press upon the Minister the various resolutions passed by recent Representative Meetings with overwhelming majorities. Instead, we have had a Negotiating Committee divided among itself and giving the Minister the impression that the doctors were not united. The Negotiating Committee should have comprised men of talent and vision but nevertheless representing the majority view of the B.M.A. instead of men with violent sectional interests and conflicting views. How comes it that the Royal Colleges, which are already represented by the B.M.A. should have eight representatives of their own on such a body? Surely this is out of proportion to their political influence on the profession.

Then, a second Negotiating Committee should have been formed similar to the present one in constitution, in order to negotiate with the Minister on Regulations and Orders. The men on this committee should be chosen for their sectional interests and would discuss details of administrative machinery

and conditions of service. But the fundamental principles of the Act would by this time have already been settled by the first committee, representing the B.M.A. only and, through it, the profession.

We have now reached a critical stage in our relations with the Government. The Minister has asked for negotiations to be started, presumably in accordance with the terms of our recent resolution. This resolution suggests very feebly that the Minister may agree during some stage of the negotiations to consider an alteration in the Act itself. It would be wrong of the Minister and the negotiating body to assume that this milk-and-water resolution reflected the true attitude of the Representative Body. This body only gave way on the main resolution as a result of verbal promises made by the Chairman of Council. But the feeling of the meeting could not be mistaken. There was a determination not to compromise on its main principles and only to enter negotiations on the certainty (not the hope) that the Act itself would be amended.—I am etc.

Newcastle upon Tyne

H. H. GOODMAN

An 84-hour Week

SIR—With your permission I would like to answer Dr R. Dingwall Kennedy and several personal correspondents. It is becoming obvious that a large number of clinics will not be established for some years. During this period doctors' wives will be confined to their homes seven days and nights a week to answer calls. To day many doctors are not providing a 24 hour service and are getting away with it. Under the National Health Service scheme doctors, after an initial fire will be directed by the Minister to find an outlet for their energies elsewhere than in the scheme. He will have the power, will use the power and in my humble opinion will be quite right to do so if we sign the contract.

My letter was written as a warning and contained a constructive suggestion. Half-day and holiday rotas can be worked out by the doctors themselves but in emergency night service should be provided by the Minister. Among other things this will obviate the need of trying to get a domestic to live in. If we are to have planning let us plan properly so that general practitioners and their wives may lead fuller and less harassed lives.—I am etc.

London S.W. 6

G. ROSEMONI

Cerebral Malaria in Great Britain

SIR—Dr P. H. Willcox (March 8 p. 310) has wisely stressed the importance of CSF examination in individuals developing fever and meningism on return to this country from endemic malarious regions. On account of the frequency of malarial relapses it is also well to stress that in these cases malaria should first of all be excluded from the clinical picture before undertaking laboratory investigations for suspected concomitant infections such as meningococcal meningitis. Negative blood films should never preclude the possibility of malaria for among all its protean forms the cerebral type (except in children) most frequently evades microscopic detection.

A full blown pyogenic meningitis on the other hand, can always be bacteriologically confirmed though investigation to this end frequently necessitates anaesthesia before cerebrospinal fluid can safely be withdrawn from a restless delirious patient.

Intravenous quinine is easily administered and in cerebral malaria response is rapid and certain except when dangerous hyperpyrexia has supervened—a threat which is surely a further incentive to its prompt administration. Rapid subsidence of symptoms establishes diagnosis or at least proclaims the dominance of malaria in the clinical picture.

Intravenous quinine is fraught with no particular danger and where rapid decline of temperature and emergence from delirium or stupor do not ensue investigation can then be directed to the cerebrospinal fluid without having lost valuable time—for time is a more urgent factor in the treatment of cerebral malaria than in any pyogenic form of meningitis. It should not be forgotten that a leucocyte count at the outset when examining for parasites, helps in differential diagnosis.

I well recall the case of a young Fren in West Africa in 1943. He was febrile and continued for 3 days before...

too all the signs of meningism, including nuchal rigidity and Kernig's sign. Blood films on admission were negative for malarial parasites but despite this and during preparations for withdrawal of CSF it was suggested that he be given intravenous quinine 10 gr (0.65 g).

Half an hour after administration delirium had ceased, and lying comfortably in bed he spoke quietly and coherently and was curious to know what had happened to him. Examination of the CSF was then carried out and meningitis excluded as a concomitant condition.

Malaria is a great simulator and while not having had the opportunity of reading Dr Walter Broadbent's letter (Jan 4 p 32) I conclude this fact was uppermost in his mind when approaching his case—I am, etc.,

London W1

A C LOVETT-CAMPBELL

SIR—In subtertian malaria schizogony takes place in the capillaries and not in the peripheral blood. If the parasites "swarm" in abdominal capillaries, cholera, dysentery, biliary colic, cholecystitis, pancreatitis, liver abscess, or even acute obstruction may be simulated. Similarly if the parasite "swarms" in the capillaries of the lungs it may simulate bronchitis, pneumonia or pleurisy. It may even invade the capillaries of the heart and give rise to symptoms resembling myocarditis. The cerebral type is due to "swarming" in the capillaries of the brain which become blocked by emboli of parasites undergoing schizogony.

In the communications published in your correspondence columns on this subject the type of parasite is not mentioned. If *P. falciparum* is absent and only the BT parasite is present, I should doubt the diagnosis of cerebral malaria as I understand it and look for some other cause of the cerebral symptoms—I am etc.

Brookwood Surrey

H M STANLEY TURNER

Retrodisplaced Gravid Uterus

SIR—I have read with considerable interest the paper (Feb 1, p 169) on retrodisplaced gravid uterus by my old colleague, Mr H H Fouracre Barns but must quarrel with his conclusion that operative treatment of retrodisplaced uterus on account of abortion is not advocated.

In patient No 39 Mr Barns records the occurrence of three pregnancies in a patient in whom a ventrisuspension operation had been carried out. There is no record of the position of the uterus in the first two, but in the third it was certainly retrodisplaced, and following correction of this displacement a successful pregnancy occurred. From this it may reasonably be deduced that the ventrisuspension operation was unsuccessful and that the uterus was retrodisplaced in the first two pregnancies. When retroversion was eliminated the third pregnancy went successfully to term, and it seems probable that the same satisfactory conclusion might have been secured in the first two pregnancies had anteversion of the uterus been ensured.

In his case No 42 spontaneous anteversion of the uterus following pessary treatment at the twelfth week was unsuccessful in preventing abortion nine weeks later. In the next pregnancy, however, the uterus was replaced at nine weeks and pregnancy proceeded to a successful conclusion. In this case the circulatory or other factors adversely influencing successful nidation in cases of retrodisplacement of the uterus were treated in the second pregnancy at a sufficiently early stage to allow of recovery and restoration to normal, whereas in the first pregnancy treated at twelve weeks circulatory factors had already caused so much disturbance that it was impossible for the pregnancy to continue.

In one of my own cases abortion occurred at 12 weeks in her first two pregnancies. On each occasion the uterus had been retroverted when she was first seen at eight weeks and had been manipulated and maintained in a position of anteversion by pessary but, in spite of this, abortion had taken place about a month later on each occasion. Following this ventrisuspension was carried out and her third pregnancy went to term uneventfully. In this patient nidation had been so adversely affected by retrodisplacement during the first two months of the pregnancy that it was impossible for the pregnancy to continue. This is in contradistinction to the second pregnancy of Mr Barns's case No 42, but in individual variation in the capability of the pregnancy of tolerating adverse circumstances is found in other connexions than retrodisplacement.

While I agree with Mr Barns's contention that habitual abortion may occur in patients with retrodisplacement of the uterus for reasons unconnected with this fact, I feel nevertheless that where abortion has occurred more than once and where

the uterus is found to be retrodisplaced there is a strong indication for ventrisuspension. As he himself has pointed out circulatory abnormalities may interfere with the imbedding of the ovum. I agree that in the vast majority of cases retrodisplacement in the early months is compatible with normal pregnancy, and I share Mr Barns's Service experience in this connexion, but nevertheless where abortion has occurred I feel that the factor of retroversion which can be so easily eliminated, should be removed by operative means—I am etc.

Inverness

J A CHALMERS

Thrush Vaginitis in Pregnancy

SIR—Much has been written on the treatment of *Monilia albicans* in pregnancy by various authors and a majority use a 2% watery solution of gentian violet. From thereon their methods of application and frequency of application, etc. vary very considerably. Several of the drawbacks to this treatment are (1) the difficulty in adequately swabbing all the folds of the pregnant vagina, (2) the discomfort to the patient, (3) the very undesirable soiling of the patient's vulva which secondarily soils her underclothing, (4) the difficulty in getting a cure by this intermittent method.

For two years now I have been getting excellent results by the following method.

The 2% solution of gentian violet is kept in a bottle with a neck not larger than 3/8 in (0.9 cm.) in diameter (internal measurements). A "tampax" tampon is held against the open neck of the bottle, and the tampon and bottle are inverted and held in this position until the gentian violet has diffused almost the full length of the tampon, expanding it slightly. A Brewer's or Cosco's speculum is placed in the vagina and the large cheesy colonies of monilia are wiped away and the tampon inserted into the posterior vault of the vagina. This is left *in situ* for a week when it is removed and replaced by another fresh and similarly treated tampon. On the average I have secured a cure after three weeks of treatment. The tampon's continuous supply of gentian violet constantly acts on any monilia present. The soiling of the patient (plus the operator and his equipment) is reduced to a minimum, for any discoloured seepage from the vagina is easily controlled by an ordinary sanitary towel worn by the patient.

With this treatment the itching and discomfort of the patient usually disappear within twenty-four hours, and a complete cure is usually obtained in two or three applications. This method lends itself very favourably to treatment in private practice—I am, etc.,

Derby

LINDSAY WATT

Achromotrichia in Tropical Malnutrition

SIR—During three years of service in the S.E.A.C. and with the occupation force in Japan I have seen a large number of nutritional anaemia cases. I am not including here those in whom anaemia was a feature of sprue syndrome. These patients were young Indian other ranks between the age groups of 20 and 30 years and almost all of them strict vegetarians. The presenting symptoms were breathlessness on exertion, progressive debility, and anorexia. They invariably ran a low grade, intermittent temperature. Diarrhoea was not a common feature until the end and the tongue was not sore. Rarely manifestations of other associated avitaminosis, like dry rough skin and pigmentation over the face were present. CNS was never involved. Haematocrit investigations done on some mostly revealed that the anaemia was of the hyperchromic megalocytic type.

In confirmation of what Capt E Roebuck writes (Aug 24, 1946 p 277), I may add that achromotrichia without any alopecia or looseness of the roots was noticed very often. Although I have not any statistical control studies I feel quite certain that the incidence of depigmentation of hair among such patients far exceeds that in the population at large. Another thing noticed was that more North Indians were treated in hospitals for gross degrees of anaemia although probably there are more vegetarians from South India in the Indian Army. They responded very well to high protein diet, iron, and vitamins, with liver administered parenterally. Blood transfusion was needed frequently and a common effect not often recorded was that the irregular temperature settled down immediately after it—I am, etc.

Obituary

BRYAN AUSTIN McSWINEY, M.B., Sc.D., F.R.S.

British physiology and St Thomas's Hospital, London, have lost an outstanding personality by the sudden death of Prof. Bryan Austin McSwiney on March 8.

An only child, he was born in Chicago on May 20, 1894, his family came from County Cork, Eire. Entering Trinity College, Dublin in 1913, he was elected the Reuben Harvee Scholar in 1915. He then became a surgeon sub lieutenant in the Royal Naval Volunteer Reserve and saw service in the Eastern Mediterranean. Recalled to complete his medical studies, he graduated B.A. in 1916, and M.B., B.Ch., B.A.O. in 1917. He took the Sc.D. (Dublin) in 1928. Commissioned as a lieutenant in the R.A.M.C., he acted as assistant to the scientific adviser of the Ministry of Food. At the end of the war he was appointed assistant to the Professor of the Institutes of Medicine in the School of Physic, Trinity College Dublin. In 1919 he became lecturer in experimental physiology in the University of Leeds. In the following year he succeeded T. Graham Brown as lecturer in experimental physiology at the University of Manchester under Prof. A. V. Hill. Here he remained for six years and began his study of involuntary muscle which was to interest him throughout the rest of his academic career. While in Manchester he collaborated with Prof. J. S. B. Stopford and the late Mr. E. D. McCrae in a study of the efferent innervation of the stomach, and with Dr. J. C. Bramwell and Prof. Hill in the measurement of pulse wave velocities.

In 1926 McSwiney was invited to return to Leeds as professor of physiology a position he was to occupy for the next ten years. During this time he accomplished much of the work that brought him a world-wide reputation. His particular interest lay in the gastro intestinal tract. Initially concerned with its motility, he became interested through the problem of its tonus, in the study of the afferent innervation of the gastro intestinal tract. In their attack on this problem the work of McSwiney and his colleagues bears all the hall marks of singleness of purpose, consummate skill in physiological experimentation, and painstaking accuracy. McSwiney's interests in physiological investigation were not confined to academic research, he realized to the full the part physiology could, and must, play in industry and he was always willing to place his knowledge and enthusiasm at the disposal of industry. In his department he gave hospitality to physiologists and chemists working on behalf of the Safety in Mines Research Board, and to others concerned with subjects as diverse as the fastness of dyes in textiles, and veterinary anthelmintics. During this period he showed a flair for organization and for laboratory design. He was chiefly responsible for the design and equipment of a new wing to house physiological and biochemical research. This building which contains an animal house, operating theatre, x-ray laboratory, workshop, and a small scale chemical plant, in addition to biochemical and experimental physiology laboratories, remains in the forefront of such design.

In 1936 McSwiney was invited to the chair of physiology in the University of London at St Thomas's Hospital Medical School, in succession to Prof. John Mellanby. In June, 1939 he learned that W. M. Boothby and his colleagues had developed an efficient mask which would deliver oxygen at high concentrations with minimal embarrassment to the subject. With Sir Henry Tidy and Dr. J. Forest Smith he journeyed to Boothby's laboratory at the Mayo Clinic. They returned the week before the war began with much of the basic equipment used to form the oxygen therapy units of the E.M.S.

When it became necessary to evacuate the hospital and medical school from London in October, 1940 McSwiney was largely responsible for their establishment in Surrey. After his appointment as Dean of the medical school in 1940 he continually concerned himself in maintaining and extending the activities of the hospital and the school and later in arranging for their re-establishment in London. He was elected a Fellow of the Royal Society in 1944, and to the London University in 1946.

Since the war he had twice visited the West Indies on behalf of the University of London to consider the possibility of establishing a medical school there. Last summer, at the request of the Colonial Office, he toured East Africa to report on medical education. He had returned from examining for the Primary Fellowship of the Royal College of Surgeons in Egypt, India, and Australasia only a week before he was taken ill with bronchopneumonia, which was the prelude to his sudden and untimely death.

Bryan Austin McSwiney was remarkable for his accessibility. He listened as attentively to the most junior technician as to the most senior surgeon or physician. He was always willing to discuss any problem, though not prone to give dogmatic advice. His enthusiasm was boundless, his encouragement infectious and he revelled in work. He believed more than most in the apprenticeship system but once the term had been satisfactorily served he gave his colleagues his complete trust and support. Many owe such knowledge as they possess of a particular subject not so much to what he told them as to the encouragement and opportunities he gave them to further their own investigations. Above all his views were sound common sense. He will be missed by many people not all within his immediate academic circle. He leaves a widow, two daughters and three sons.

Mr. John B. Hunter writes: The news of the death of Bryan McSwiney will have come as a great shock to his many friends and colleagues. He came to London with a great reputation as a physiologist both as a teacher and research worker, having held several appointments in the provinces. Shortly after his arrival he showed he was also a man of affairs. He was in great part responsible for the promotion of the resuscitation units that were formed during the war bringing his physiological knowledge of shock to the practical side of resuscitation. In 1940 when he was appointed Dean of St Thomas's he became known to a wider circle in the University of London. His gift of clear thinking and his administrative qualities were soon appreciated and he became secretary to the Conference of Metropolitan Deans and a member of the Collegiate Council of the University and later a member of the Senate. It was my good fortune to be associated with him in these activities and together we travelled some thousands of miles on a Colonial inquiry, and I came still more to appreciate his likable qualities and his sense of humour chiefly shown in his appreciation of the ludicrous which does so much to keep our sense of proportion. His advice in connexion with medical education in the West Indies and Africa will be sorely missed in the University of London and the Colonial Office—for he had wide knowledge of the subject gained at first hand in the Colonies—as will his counsel on medical education in this country.

R. J. GLADSTONE, M.D., F.R.C.S., F.R.S.E.D.

The anatomical world will mourn the death of R. J. Gladstone on Feb. 12, for, although he did not hold a chair of anatomy, he was one of the best known members of the Anatomical Society of Great Britain and Ireland for over fifty years. He was born in 1865 the son of Dr. T. H. Gladstone and was educated at Clapham Grammar School and the University of Aberdeen, where he qualified M.B., Ch.M. in 1888. After leaving Aberdeen he became house-physician and later house-surgeon at the Middlesex Hospital. Having a bilateral congenital contract, he decided to make anatomy his special field of work, and was appointed junior demonstrator in anatomy at the Middlesex Hospital Medical School in 1895. The following year he was promoted to senior demonstrator of anatomy and took his final F.R.C.S.

By this time Gladstone had already started to publish some of his original papers, and in 1905 he went to Vienna with Dr. R. A. Young to investigate methods of teaching anatomy and surgery. A year later he visited Vancouver as a representative of the British Medical Association. He made new contacts and friends and came back to this country with fresh ideas on the teaching of medical students. He continued his association with the Middlesex Hospital in 1913 when he became reader in anatomy at King's College London, a post he held until his retirement in 1929. He had a very extensive knowledge of anatomy, anthropology, and embryology. He was a thorough master of his subject.

to say that Gladstone had a better knowledge of human and comparative embryology than any other anatomist of his day.

Gladstone was a born worker and put in a very full day in the anatomy department. He did his full share of demonstrating in the dissecting-room, and in this respect was an example to those senior demonstrators who consider their job is purely research. At night he worked on the many papers that came from his pen. He loved music and was always delighted to attend any musical show that medical students organized. He was an ardent supporter of the Zoological Society and spent most of his Sundays in the gardens making friends with a variety of different animals.

He could not see clearly beyond a few feet, and this no doubt was his greatest handicap in life, as he could not see the pranks his students were performing during his lectures, and he would have found it difficult to have had sole charge of a department. Although the students ragged him and were liable to be somewhat uproarious during his lectures, he was very popular and was affectionately known as "Gladeye." He worked hard for the Anatomical Society and put in many years as Recorder, his notes of meetings were a model for any successor to emulate. He rarely missed a meeting and was always willing to help the younger members of the Society. He never pushed himself forward and was always content to take a back seat. When he spoke at meetings his remarks were constructive and had practical experience as their main background.

Gladstone wrote with Cecil Wakeley a book on the pineal organ, which is a most comprehensive volume and one which has been styled as the most practical and valuable work that has ever been published on that subject. In 1930 he began to write a textbook on human embryology, but this has never been completed. This was because as soon as he finished one section he wanted to revise it and bring it up to date. He completed over 500 drawings for this book, and anatomists the world over are the poorer for its non-appearance. He married in 1912, and a son and a daughter completed a very happy home. He often worked far into the night, and was meticulous regarding the facts and figures that appeared in his writings. For many years he was a valued contributor to the columns of the *British Medical Journal* and he had been a member of the B.M.A. for over fifty years.

He was a lovable and meek man who turned the other cheek rather than speak out against those who did not agree with him. When he retired from King's College he spent his time abstracting medical literature, or else reading proofs and verifying references in medical articles passed for press. His house in Dulwich was bombed in 1941 and he had to move. He found a new home at Brockenhurst, where he continued his work until a few days before his death. Gladstone was a born artist and illustrated his many papers with excellent drawings. His daughter has inherited this talent. Gladstone left a wealth of embryonic material behind him at King's College. There are series of sections of human embryos, all carefully documented, which should prove of the greatest value to students of anatomy and embryology.

LOUIS COBBETT, M.D., F.R.C.S.

Dr. Louis Cobbett was taken ill at his home at Cambridge on March 9, and died in hospital the next day at the age of 85. Louis Cobbett was born in 1862 and was educated at Lancing and Trinity College, Cambridge. After leaving Cambridge where he had come under the influence of Sir George Humphrey, he went to St. Thomas's Hospital obtaining the Conjoint Diploma in 1890, the Cambridge M.B. in 1892 and later the F.R.C.S. He was house surgeon to the late Sir William MacCormac. He proceeded M.D. in 1899 with a thesis "On the nature of the action of antitoxin."

He returned to Cambridge in 1893 as demonstrator of pathology under C. S. Roy, the first professor of pathology in the university. In 1894 he resigned the demonstratorship and became John Lucas Walker student, a post he held till 1897. In 1894 he became interested in diphtheria, especially in the production and effects of antitoxin and in the cultural characteristics of the diphtheria bacillus. During the next few years he published several papers on these subjects. In 1900 outbreaks of diphtheria in Cambridge and Colchester gave him the opportunity of tracing the spread of the disease by the examination

of school and other contacts. He investigated the virulence of cultures from all patients and infected contacts, and in order to check the spread of the disease arranged for the isolation of the latter till the bacilli had disappeared from their throats and noses. His work was among the first large scale investigations of this type.

In 1902 he was appointed scientific investigator to the Royal Commission on Tuberculosis, with charge of one of the experimental farms at Stansted. The well-known results of his work there were published in an appendix to the Royal Commission's report of 1907. For about a year he held the professorship of pathology in the University of Sheffield and then returned to Cambridge in 1908 on his appointment to the lectureship in pathology, a post he held till 1929. During this period he taught with great enthusiasm and published many papers chiefly on the mode of spread of tuberculosis. After retiring from the lectureship he worked in the department of pathology, mainly on the bacteriology of tuberculosis, and gave courses of lectures to students taking Part II of the Natural Sciences Tripos. He had been a member of the British Medical Association and acted as vice-president of the section of pathology and bacteriology at the Annual Meeting in 1920.

According to a correspondent Dr. Cobbett was remarkable for his kindly disposition, his keenness in teaching, his interest in and kindness to the junior assistants in the department and his enthusiasm in discussing every subject in which he was interested. He was unmarried.

Dr. PRIDEAUX GEORGE SELBY died at the age of 81 on Feb. 26. Dr. Selby was born in 1865 at Dunedin, New Zealand. He was educated at Bedford Grammar School and at St. Bartholomew's Hospital. After qualifying in 1887 he studied for a while in Vienna. In 1890 he started in general practice at Teynham, Kent, and was soon after appointed medical officer of Beacon Hill Hospital in the old Faversham Rural District Council. In 1905 he succeeded the late Dr. F. A. Genge as medical officer of health for that district. In 1935, when the Faversham and Milton rural districts were amalgamated to form the present Swale Rural District, Dr. Selby retired, but on the death of his successor, Dr. Wernett, he resumed duty as acting medical officer of health pending a new appointment. When war broke out it became impossible to make such an appointment and Dr. Selby had loyally carried on ever since. A great deal of work devolved on him in organizing and superintending A.R.P. work in this locality, and many bomb incidents had to be attended to in addition to his ordinary work. He sold his general practice in 1943, but continued his work as acting M.O.H. until his death. During the war of 1914-18 Dr. Selby served with the rank of major in the R.A.M.C., and was awarded the O.B.E. Dr. Selby contributed two short articles to this *Journal* at the end of the last century and in January last we published a letter from him on the discovery of chloroform. He had been a member of the B.M.A. for just under sixty years.

Medico-Legal

A CONFLICT OF EVIDENCE

The Cornock Case

The trial of Mrs. Rosina Ann Cornock, who on March 7 was acquitted at Bristol Assizes, furnished an unusually striking and complete conflict of medical evidence.

Mr. Cornock was addicted to masochistic practices in which his wife took part and on the evening of Friday, Dec. 6, 1946, the day before his death, she had at his request tied up his wrists and ankles and beaten him. A young cripple called Gilbert Kenneth Bedford, and said to be in love with her, was staying in the house with the couple for the week end (as he often had before). He saw the scene through a glass-pannelled door. At some time after 1 a.m. on Sunday Dec. 8, Mrs. Cornock called an ambulance, and at 2 a.m. Dr. G. R. Fells found Mr. Cornock's dead body laid in a bedroom. The head was bruised in five places, the shoulders and elbows were injured, the small of the back was abraded, the knees and shins were bruised, and the wrists and ankles were rope marked. Torn-up love-letters written by Mrs. Cornock and Bedford to

each other were found Mrs Cornock was on Feb 7 last two months pregnant

The Crown suggested that she had again tied Mr Cornock up at his request and taking advantage of his helplessness drowned him in the bath. Her own story was that she did not love Bedford and her child was her husband's, by an act of intercourse about a fortnight before his death. On the Saturday evening, when Bedford was out the husband had insisted on another act of perversion (not specified but described by the prosecution as "disgusting and incredible"), and afterwards she had prepared a hot bath for him. He had gone up to take it between 10.30 and 11 p.m. Bedford had come in just then. After what seemed a long time she had gone upstairs and found her husband lying in the bath with one leg on either side of the top edge and his head under water. She had felt his pulse, which had stopped and had pulled out the plug. She and Bedford had dragged him out dropping him back once, and again on to the floor and a part of the geyser had broken off and wounded his shins. In the bedroom she had performed artificial respiration on the body for three quarters of an hour. Realizing that this was hopeless she had summoned help.

The medical evidence therefore, became highly important. Dr A. D. Fraser, honorary pathologist at Bristol Royal Infirmary, gave the cause of death as asphyxia by drowning. On a wax model head he demonstrated the five separate severe blows which he said could have been caused by a toy boat about a foot long produced. He said the injuries to the shoulders, elbows, and knees were caused before death possibly by the sides of the bath during a struggle. The abrasions on the small of the back could have been brush burns made by friction of a rope. He would not expect a man to faint in a bath from exhaustion due to the perverted practices described.

On the other side Dr C. R. Gibson, surgeon to the Bath City Police, said that the scalp injuries were consistent with heavy bumps on a flat surface when the heart's action was feeble. The injuries on the shoulders and elbows could not have been caused either by rubbing or by hitting the sides of a bath full of water but might have been caused by the body being dragged or dropped. The marks on the knees could not have been made by the knees being rubbed together, but could have been caused in a small bathroom by the body falling on the ground from the edge of the bath and then being rolled over on to the face for artificial respiration. He had verified by experiment on himself that rope marks on his wrists made an hour before a bath would show as bruises afterwards. To the prosecuting counsel (Mr G. D. Roberts, K.C.) he answered that the explanation of a struggle for life in the bath would be a very easy but a very bad one. Dr A. L. Taylor, honorary pathologist at Bristol General Hospital, said that the toy boat was an extremely unlikely instrument to have caused the head injuries, and the back injuries could have been caused by the dumping of the body on the floor.

The medical witnesses were agreed, therefore, that the injuries were caused during life. They disagreed almost entirely on the means by which they could possibly have been inflicted. This disagreement must have contributed greatly to the reasonable doubt which led the jury to acquit the prisoner.

Universities and Colleges

UNIVERSITY OF OXFORD

In a Congregation held on March 1 the following medical degrees were conferred:

D.M.—W. E. Gibb
B.M.—Elizabeth M. C. Dyke

UNIVERSITY OF CAMBRIDGE

The following candidates have been approved at the examination indicated:

M.Chir.—R. L. Canney, A. S. Till, W. W. Wiggins Davies.

Thomas Renton Elliott, M.D., F.R.S., Emeritus Professor of Medicine in the University of London, has been elected into an Honorary Fellowship of Trinity College.

The Linacre Lecture on "Man's Place Among the Primates," will be delivered by Prof. F. Wood Jones, F.R.S., in the anatomy school of the University on Tuesday, May 6, at 5 p.m.

Medical Notes in Parliament

SCOTTISH HEALTH SERVICE BILL

The Standing Committee on Scottish Bills considered on March 11 Clause 35 of the National Health Service (Scotland) Bill. This Clause deals with compensation for loss of the right to sell a medical practice.

Cmdr GALBRAITH proposed that compensation should be paid forthwith or as soon as practicable after the appointed day or the day on which the medical practitioner to whom it was payable was entered on a list of practitioners undertaking to provide general medical services. It was wrong that a person should not be compensated immediately for a realizable asset. Why should doctors be forbidden to receive compensation until they died or retired or until they fell into line with some circumstances which the Secretary of State would lay down in his regulations? The doctor might have borrowed money to buy the goodwill of his practice and might wish to repay the loan but he was not allowed to do so. So far as Cmdr Galbraith could understand the Clause the interest on the doctors' compensation would accumulate. He did not see why this interest should be withheld. A doctor who had purchased the goodwill of a practice and had practised for two or three years might want to specialize and might require something in his pocket to enable him to do this. Under the Clause that opportunity was taken away from him and from the doctor who wished to secure the payment for the purpose of educating his children or in order to accept a post in one of the big infirmaries.

Arrangements for Compensation

Mr BUCHANAN secured the approval of the Chairman for an enlargement of the discussion to cover a subsequent amendment to permit payment of the compensation when the practitioner reached the age of 65. Mr Buchanan said he could give a general outline of the proposed regulations. The English Act dealt with this exact question in regard to England. The British Medical Association was a body which dealt with the whole of Britain and negotiated for Britain as a whole. If an alteration were made in the terms of the Scottish Bill the Government would need to pass an amending Bill altering the English Act. If doctors particularly young doctors had bought their practices and incurred substantial debts the Government proposed to pay. The Bill covered the case of a doctor who sold his practice and decided to take a hospital appointment. If a doctor took a local authority appointment or became a works doctor the Government would also pay him. The only case in which it would not pay was that in which a doctor remained in practice. There was no hardship there. Where a doctor proposed to buy another practice he almost certainly would pay as much for the new practice as he would for the one he was quitting. So there was no hardship. In the case of retirement the Government proposed to pay, and the position of a doctor going overseas to practise would be the same. The only persons who would not get compensation would be the doctors who remained in practice. The Government had gone out of its way to meet all possible contingencies.

Col ELLIOT could not agree that a doctor moving from one practice to another would normally be exchanging like for like. A doctor in a large industrial practice looked forward to taking at a later stage of life a smaller practice in the country. That was a very old custom and Dr Johnson had referred to it. Did Mr Buchanan say that in such a case the doctor must surrender the unexhausted goodwill of the medical practice in the industrial area and be compensated when he finally retired on the basis of a small practice in a remote part of the country? He asked whether Mr Bevin was in negotiation with the medical profession on these points. The sale of practices was a matter to which the profession attached great importance and on which they looked forward to considerable concessions from the Minister. As Mr Buchanan had said the English Act and this Bill were closely linked and in any negotiations doctors in Scotland ought not to come off worse than doctors in England.

Mr BUCHANAN said Scottish doctors would be treated equally with English doctors. The Government would bear in mind the issue of semi-retirement. That was the only issue it had in mind.

Mr SOMERVILLE HASTINGS hoped Mr Bevin would look at this matter again. No doctor should enter the new Service with a sense of grievance. Many doctors had approached Mr Hastings on this matter of retirement and would in many cases rather have some ready money at once. Many doctors wished to take an easier job or to buy a smaller house and to have a sense of security knowing that they had this little

ouse when they retired Means should be found to enable doctors to claim their retirement money before the day on which they left the Service

Mr BUCHANAN said he wished that Mr Somerville Hastings could have done all this in connexion with the English Bill

Mr HASTINGS said he did try

Major LLOYD said every medical man knew there was a grave risk in the present state of the country that the value of the pound would fall materially before deferred compensation was paid In view of Mr Buchanan's statement Cmdr Galbraith withdrew his amendment and Clause 35 was ordered to stand part of the Bill Clause 36 was also ordered to stand part as was Clause 37 on which a drafting amendment was made

Pharmaceutical Services

On Clause 38 Mr REID raised the question of the transport of drugs and medicines from the manufacturers to the chemists shops He pointed out that ordinary transport organizations might not be able to undertake this work efficiently Mr BUCHANAN said that his Department was in consultation with the Ministry of Transport The interests of the chemists would be safeguarded

On Clause 39 Mr MCKIE suggested that subsection 1 would prevent the medical or dental practitioner from providing pharmaceutical services to any person to whom he rendered general services

Mr BUCHANAN said that in almost nine tenths of the cases in Scotland the chemist rather than the doctor did the dispensing Even in rural districts the chemists did most of the job except in the Highlands and Islands In rural areas where the circumstances were similar to those in the Highlands and Islands the Department proposed to make regulations whereby the doctor would be able to dispense as well as the chemist Medical skill should be utilized in the main for more important branches of work while the chemist carried out the dispensing Col ELLIOT said that although an orthodox practitioner, as a citizen he admitted that those who did not believe in orthodox medicine had the right to be provided for These persons wanted to be sure that the Clause would not preclude the making, for example, of a herbalist prescription He wanted to be assured that the homoeopathic system of medicine, in which he did not himself believe, would still be possible

Mr BUCHANAN said the answer was yes, provided everything was prescribed and dispensed by people with proper qualifications

Dr MORGAN said there was no such thing as a herbalist's prescription

Disqualification of Doctors

Clause 39 was ordered to stand part, and Clause 40, on supplementary ophthalmic services, was accepted without discussion On Clause 41 Cmdr GALBRAITH moved to leave out the words 'prejudicial to the services in question' in the subsection providing a tribunal for inquiry into the conduct of practitioners He proposed to substitute "detrimental to the interests of his patients" He said the words proposed to be left out were very wide If a practitioner was remiss in sending in his returns or sent them in wrongly made out, this would be prejudicial to the services but not to the interests of his patient It might be that he was treating his patient so well that he had not time to devote himself to compilation of the returns

Mr BUCHANAN said he had been attracted by the amendment but it was not easy of acceptance A doctor might be asked to render a service to another doctor in emergency, but might flatly refuse to help That would not be detrimental to his own patients, but would be against the well-being of the Service as a whole On the other hand Mr Buchanan did not want to have doctors 'kicked around' because they drove a motor car too fast or had a quarrel with a policeman A good deal of the wording of the section was from the National Health Insurance legislation, about which there had been no complaint He would look into the matter again before the Report Stage but could not agree to insert the words "his patients"

Mr REID suggested the words 'interests of those requiring his professional services' He remarked that it had been much easier for a doctor who had been turned out from the National Health Insurance scheme to make an alternative livelihood than it would be in the future A kind of medical law was being started and in law it was essential to have a specification of crimes and offences as well as a judge who would understand the position

Mr BUCHANAN agreed that any man charged must know specifically with what he was charged

Sir JOHN GRAHAM KERR thought there was great danger in the proposal of the Bill that representations against a doctor could be made by 'any other person' Such representations might be actuated by jealousy or other personal feeling

Mr BUCHANAN said he would look at that issue The Committee must remember that the Scottish Health Service would be linked inevitably with England Dismissal in one country carried with it dismissal in the other and it would be indefensible that conditions should differ in the two countries

Dr MORGAN said doctors had been penalized unnecessarily for offences which were social and personal and not professional The British Medical Association now had a committee discussing the whole question of these offences in relation to the General Medical Council Income tax inspectors had threatened to bring doctors before an insurance committee for not paying their taxes promptly

The amendment was withdrawn and Mr REID moved another amendment to challenge the provision that a man could be taken off the list for a particular area but left on the list for another district If his activities were injurious to district A, why were they not injurious to area B? There ought to be something short of removing a man completely from all lists He suggested some fine or suspension for a short period

Shape of Things to Come

Mr BUCHANAN could not accept the amendment In his local government experience he had known that it was a good practice to transfer a policeman from one district to another but not to sack him That might apply to doctors Doctors could get into bad company just as Members of Parliament could He was not keen on fines if these could be avoided To fine a doctor £50 or £100 might be disastrous to him A change from one district to another was the best way He had known a case where it was good for a sheriff when he was shifted back to a big city and was given harder work to do

Col ELLIOT asked the Committee to note the length to which regimentation was inevitably carried under the Bill The mind of Mr Buchanan was running on the analogies of whole time service by the sheriff and the policeman in connexion with power to transfer from one place to another To Mr Buchanan he said, 'Do not interfere unless the offence is so grave that it would prejudice the chances of the patient being successfully treated' To say "this man is unpopular here but he would do well somewhere else" meant involvement in local squabbles and might stultify the practice of medicine

Dr MORGAN said the General Medical Council had now adopted a process by which a man was found guilty but was not struck off He was asked to come before them again in six months or a year with testimonials from consultants in the area

The amendment was withdrawn and Mr REID moved to delete the subsection dealing with appeals and to substitute a provision that any person aggrieved by a direction of the tribunal might appeal to the Court of Session, whereas the subsection proposed an appeal to the Secretary of State In recounting the previous stages before an appeal Mr Reid said he understood that if the tribunal acquitted the doctor the Secretary of State would then appeal to himself

Mr BUCHANAN said that if the tribunal acquitted a doctor the Secretary of State had no power whatever Mr REID said that in that case Mr Buchanan had thrown over Mr Bevan and the whole of the argument by which the English Minister sought to justify this Clause Mr Bevan had said 'I must have the last word in every case I must have it in my own hands to sack a doctor I cannot trust and I will not delegate that to any tribunal or court' To his credit Mr Buchanan had recognized that that was an impossible position If Mr Buchanan said that he was content to accept the judgment of the tribunal that the man was all right why could he not be content to accept the decision of the Court of Session?

Mr BUCHANAN said he did not know that Mr Bevan had made a speech on this subject He was not bound by some body else's speeches He had consulted the Lord Advocate and there seemed no doubt that there was no appeal by the Secretary of State against acquittal An aggrieved doctor had an appeal to the tribunal legal members of which were appointed by the Lord President of the Court of Session The chairman would be appointed by someone connected with the legal profession The Eighth Schedule of the Bill said this chairman was to be appointed by the Secretary of State, but the Government had an amendment down making it clear that the President of the Court of Session would do it The tribunal would examine not questions of law but questions of fact In his view the decision would be final and binding If on the other hand, an aggrieved doctor appealed to the Secretary of State he would have a further right of appeal to have his case taken up on the floor of the House of Commons This could be done by some unorthodox doctor who was raising wider issues At present doctors in Britain in private practice could be dismissed from National Health Insurance without any tribunal, but in fact this had rarely happened and the number

Early symptoms of Vitamin B deficiency are frequently overshadowed by the seriousness of the underlying condition—pregnancy obesity disease. For patients in danger of developing B vitaminosis because of reduced intake, increased demand or poor absorption, Beplex Capsules can be prescribed with confidence.

Three Capsules will provide—Thiamine Hydrochloride 1000 gamma, Riboflavin 800 gamma, Nicotinamide 10 000 gamma, Pyridoxin 12 gamma, Pantothenic Acid 13 gamma.

LAST-MINUTE ANTE-NATAL ROUTINE

the place of vitamin K analogue

Last-minute ante-natal measures include prophylaxis against neo natal hæmorrhage a consequence of the usual fall in prothrombin blood levels in the newborn. The vitamin K analogue Kapilon administered to the mother 4 to 2 hours before delivery will effectively raise the prothrombin blood level in the baby. Kapilon, a synthetic vitamin K analogue exerting the physiological action of vitamin K itself, can be given orally (tablets or liquid) or, if necessary by intramuscular injection. Neo-natal hæmorrhage which contributes so much to infant mortality in the first few days of life is thus brought within the sphere of preventive medicine.

To combat the Depression of Chronic Organic Disease

Many patients with chronic organic disease sink into a persistent depression, characterized by discouragement and even despair. Unless effectively combated, this depression may intensify the symptoms of the basic disorder and handicap its treatment. By restoring optimism and interest in useful living, 'Benedrine' Tablets frequently help to overcome prolonged depression accompanying chronic illness and thus facilitate the general management of the case.

of cases which the Secretary of State would have to decide would be so small that he would have to examine them with the greatest care. The amendment was rejected by 21 to 14 and the Committee adjourned.

Reasons for Disqualification

On March 12 Mr McKIE said Clause 41 offered many sources of danger to the medical profession. It placed too much power in the hands of the Secretary of State for Scotland and in the tribunal of three persons which it proposed to set up under the direction of the Secretary of State. The powers given to the tribunal were excessive and the Clause as at present drafted opened the door to snooping and to possible denunciation of a person who was innocent, particularly in the rural area where there was always much gossip.

Mr GALLACHER supported the Clause because under it doctors and dentists who felt a grievance could go to their Members of Parliament and get them to make a fight on their behalf.

Mr REID said the doctrine of an appeal through the House of Commons depended entirely upon bringing political considerations to bear. It was thoroughly wrong. Let the Committee avoid mixing up politics and a judiciary. The Clause did not confer the right of cross examination of hostile witnesses. He also asked whether reasons would be given when the decision of the tribunal was published. A judge always gave reasons and those who sat as judges should also do so.

Mr BUCHANAN said the right of cross examination would be strictly safeguarded. As to publication, he would look into that. It might be that the published reasons for a dismissal of a doctor might damage him even in his chances of getting any work abroad. Mr Buchanan thought that the doctor himself must receive the reasons. So must his legal representative. The case to be settled on an appeal was not a legal question but a question of fact. Such cases should not go to the Court of Session. He pointed out that more than 95% of the practising doctors in Scotland were concerned in National Health Insurance and in the past thirty five years only about a dozen cases concerning them passed through. Yet there were none of the safeguards for them which the Bill provided. When occasionally a man's dismissal had been raised in the House of Commons the subject was above ordinary political difference.

Cmdr HUTCHISON asked whether under the Crown Proceedings Bill which had been introduced in the House of Commons it would be possible for a doctor dismissed from the public service to sue for wrongful dismissal.

Mr BUCHANAN said he was told by the Lord Advocate that the answer was Yes. Clause 41 was then ordered to stand part of the Bill.

Powers of Secretary of State

On Clause 42 Mr REID moved to leave out the provision that the Secretary of State may dispense with any of the requirements of regulations made under this part of the Act so far as appears to him to be necessary to meet exceptional circumstances. Mr Reid said this was a wide and dangerous form of power.

Mr WESTWOOD said this was not a new power and would only be used in exceptional circumstances. It had been in operation under the National Health Insurance Acts since their inception.

Sir WILLIAM DARLING asked if the Secretary of State could give an example of an exceptional circumstance which he had in mind.

Mr WESTWOOD: I say quite frankly I cannot.

Col ELLIOT said these general powers had been in the possession of the Executive for a long time and should continue there. The fact that no Secretary of State had used these powers indicated that on the whole the medical system of treatment had worked out fairly well. What the Opposition felt uneasy about was the narrow point of the permission for the Secretary of State to dispense with the requirements of regulations. A modification of a regulation ought to be brought before Parliament. These powers which were intended for bringing the new Service into smooth action should have a time limit placed upon them.

Mr WESTWOOD promised to look into these points and Mr Reid's amendment was withdrawn. After further discussion Clause 42 was added to the Bill.

Charges and Disputes

Mr MCPHERSON moved an amendment to Clause 43 to make the regulations under this Clause mandatory. The Clause concerned the recovery of charges in respect of certain appliances and dental treatment.

Mr WESTWOOD said the Government proposed to have the highest standards in health and sight and in all the things that made life worth living. The amendment was withdrawn. A

similar amendment dealing with expensive forms of dental treatment was also withdrawn. The Clause was ordered to stand part of the Bill.

On Clause 45 Mr REID moved an amendment proposing that the Secretary of State, before deciding a dispute between an executive council and a person receiving or claiming services under the Act, should afford both parties an opportunity of appealing before someone appointed for the purpose by the Secretary of State. Mr Reid said this Clause dealt with all manner of complaints which members of the public might make about services from doctors, dentists, or opticians. If someone of experience in these matters was not to hear the complainants, they would write to their Members of Parliament and the Members would have to do the investigating.

Mr WESTWOOD gave an assurance that where a complaint was substantial and a person desired a hearing arrangements would be made for that hearing to take place. The amendment was withdrawn and Clause 45 was ordered to stand part of the Bill as was Clause 46.

Mental Defectives

On Clause 47 Col ELLIOT pointed out that under subsection 3 certain institutions were not to be brought in under the Bill. These were institutions established under subsection 1 of Section 28 of the Mental Deficiency and Lunacy (Scotland) Act, 1913 for defectives of dangerous or violent propensities. He asked Mr Westwood to name these institutions.

Mr WESTWOOD said the only existing institution of the kind was at Perth prison. That was the only exemption he had in mind at the moment.

Sir BASIL NEVEN-SPENCE referred to the provision in the Clause dealing with the duty of the Secretary of State to co-ordinate and supervise the administration of education authorities and local health authorities with regard to defectives. He said high grade mental defectives were provided for in special classes and special schools but the case of the lower grade defectives was not so happy. They were passed on to the public assistance authorities. Prof D. K. Henderson who was well informed on these problems, said the question was primarily a health one and that the health authorities should be responsible for looking after these children. Sir Basil was sorry that there was no reference at all in the Bill to ascertainment. That should be dealt with under Clause 47 which mentioned the Mental Deficiency and Lunacy Act. The duty of ascertainment of mental deficiency in children between the ages of 5 and 16 had been placed on the education authorities under the 1939 Act but these authorities had not carried out their duties. Another defect in the Clause was that it did not bring in the mental defectives under 5 years of age. The only action open to a local authority was to have such a child certified as a lunatic and sent to a mental hospital.

Mr WESTWOOD said the Clause did not go as wide as he would like it to do. The Bill did not seek to implement the recommendations made by the Russell Committee. The Government was going into that matter and a separate piece of legislation was required. Clause 47 was then ordered to stand part of the Bill. On Clause 48 Col ELLIOT moved an amendment in order to secure information in regard to the discharge of patients.

Mr BUCHANAN said at present there was a difference between the person who could pay for treatment and the person who became a pauper lunatic. The private patient could get out of an asylum or out of a place of detainment at the request of his own relatives provided that the superintendent of the institution certified that this discharge created no danger to the public. If that was good enough for the private patient then the person who was receiving poor law relief should have the same rights. If the superintendent thought that either of these was a danger in any way to the community he had the right to retain the patient. The second point was that a pauper could be returned on one doctor's certificate while a private patient must have two certificates. The Bill made two certificates requisite for both classes of patient. The Government was also making it the law that a local authority should be reasonably satisfied there was a proper place in which both classes of persons could be looked after.

Mr REID said his friends were delighted to hear of the change in regard to certification but he was not so happy about discharge. Mr Buchanan had said the last word was with the superintendent. Mr Reid had occasion to think that superintendents, no doubt owing to war circumstances were letting out too easily persons who had been convicted or had been found to be insane and had been put into asylums at the instance of the procurator fiscal.

Mr BUCHANAN said the Government was not interfering with the present law but asked that the treatment of persons under poor law relief should not differ from that of others.

SIR BASIL NEVEN-SPENCE said there were people who recovered and were released yet were a menace to the community. It was not the job of the medical superintendent to keep these people in an asylum if they recovered. Col ELLIOT withdrew the amendment.

SIR BASIL NEVEN-SPENCE said that at present there were fifteen poorhouses in Scotland in which 1,300 pauper lunatics were kept. This perpetuated an association of mental health with the poor law which should have been broken long ago and he was glad that subsection (b) of the Clause made it unlawful to retain lunatics in poorhouses. The Clause was ordered to stand part of the Bill, as was Clause 49.

Payments to Regional Boards

On March 15 Clause 50 was ordered to stand part of the Bill with a drafting amendment. The Committee also approved Clause 51, after accepting an amendment moved by Mr Buchanan.

On Clause 52 Mr REID asked for an assurance about the method of financing boards of management. He said the Clause provided that all money must be paid in the first instance to regional hospital boards.

Cmdr HUTCHISON pointed out that money could be provided for the expenses of a tribunal constituted under Clause 41. He asked whether that would cover expenses for a person who appeared before a tribunal.

Mr BUCHANAN said he would answer that on the Report stage. On the point raised by Mr Reid, the Government proposed that the management committee would make up a budget each year. It would pass that budget to the regional board which would make a gross budget, covering all the management committees and its own work, and would submit that to the Treasury.

SIR JOHN GRAHAM KERR asked whether there would be means of meeting exceptional hospital expenditure such as occurred when a member of the staff introduced a new method of treating an ailment, a method involving considerable expenditure on premises or appliances.

Mr BUCHANAN said in such a case there would be no difficulty in having a supplementary grant for that particular purpose. The Clause was ordered to stand part of the Bill as were Clauses 53, 54, 55, and 56, with a minor amendment on Clause 54.

Mr REID asked why the capital or income of any trust must under Clause 57 be paid to the regional hospital board for the area.

Mr BUCHANAN said the trustees would decide this matter themselves. They could either pay the money to the board of management or to the regional board. They might take the view that the money should be paid to the particular hospital or that it concerned not one hospital but a group of hospitals.

Denominational Hospitals

On Clause 58 Mr REID hoped that other hospitals with a special character would be entitled to preserve that character. He had in mind the homoeopathic hospital or one staffed and run entirely by women for women.

Mr BUCHANAN referring to the denominational hospitals, said he agreed with Mr Reid that there were other similar cases. There were the temperance people who ran a hospital. The Government would try to preserve the character of such hospitals and to get people competent to carry them on but he could not put in a clause to cover every kind of hospital. He refused to try to give a definition of "denomination." If any group of people who formed themselves into a religious body had a hospital then the Government would recognize it. The Clause was ordered to stand part of the Bill as were Clauses 59 to 62.

Mr REID said Clause 63 took power to make regulations on the remuneration and conditions of service of all Government employees. It also made regulations of the same character for all local authority servants employed by an authority as the health authority whether their job had anything to do with the Bill or not. He moved an amendment to make it possible for the Government to make regulations only about the conditions of service of people who performed the functions set up by the Bill.

Mr BUCHANAN said a dentist might be mainly but not entirely employed by the Government. The agreement with him was a national agreement. The Government wished to ensure that for the small proportion of time he worked for another authority he should not work for a different rate of wages. However, he would look into the matter again.

"Closed Shop"

Mr REID withdrew his amendment and moved to insert a proviso that it should not be made a condition of service for any officer that he should or should not belong to a trade

union. He recalled that Mr Bevan last autumn had done all he could to dissuade local authorities in places near London from attempting to enforce membership of trade unions on nurses and others. He said it would assist recruitment of nurses if Mr Buchanan would put into the Bill words to ensure that none of his successors would be entitled to amend the regulations by putting in a "closed shop" condition of this kind.

Dr MORGAN submitted that the proviso should not be put in an Act of Parliament. It should be left to the discretion of the local authority. The recent fight at Willesden was between two organizations—one a trade union and the other an association. Mr Reid's amendment would give local authorities power not only to say that a person should join or should not join a trade union but that they should or should not be a member of an association.

Mr MACPHERSON said it was customary for members of certain professions to belong to associations. The Bill provided that qualifications could be laid down by the Secretary of State but that was a different matter from membership of an association.

Mr BUCHANAN said this was a health Bill and to insert into it an amendment of this kind would do great disservice to the health services of Scotland. The great voluntary hospitals of Scotland could never have carried on if they had not had the financial assistance and enthusiasm engendered by the trade union movement. To single out this movement by an offensive amendment like this would be entirely wrong. The Scottish Health Department had recently communicated a circular to Scottish local authorities. This informed them that while the Secretary of State was anxious that doctors, nurses and members of similar professions should join a trade union or appropriate professional association he considered that the matter should not be determined by the unilateral action of local authorities.

The amendment was defeated by 25 to 11 and the Clause was ordered to stand part of the Bill.

On Clause 64 Mr BUCHANAN said the Government proposed to take over everybody who had a superannuation claim and to pay that claim but not to give more. If a man had a reasonable expectation of getting a pension the Government proposed to pay that pension, but it would not add anything. Replying to Dr Morgan, Mr Buchanan said he thought that officers due to retire on a pension at the age of 55 would be allowed to continue in service until the age of retirement under the new Insurance Act. Clause 64 was ordered to stand part of the Bill and the Committee adjourned.

Extra Rations for the Sick

Col STODDART SCOTT on March 10 raised the refusal of the Ministry of Food to grant extra rations to sick people when their doctors recommended that they should have them. During the last six months 235 such cases had been refused extra rations. He suggested the establishment of regional medical advisory committees appointed by the Minister of Food. He further suggested that extra food should be given not only for treatment or cure of disease but also to relieve suffering in cases of operation or in inoperable cases.

Mr SOMERVILLE HASTINGS said the public and the medical profession were satisfied with the arrangements in existence. These seemed to him to be working admirably. The position of the doctor in private practice was not easy and was much strengthened if in refusing a patient's request he could say that the case did not come within the confidential list of diseases for which extra nourishment could be authorized.

Dr SUMMERSKILL said it was not true that the incidence of disease had been greater during recent years while the country was rationed. The Ministry had to maintain a balance between the physiological needs of the community as a whole, and the medical necessities of those suffering from some pathological condition. It had to provide for the children under 5 for nursing and expectant mothers, and for young people up to 18. In regard to hospitals and in the case of invalids treated by a private doctor, the Ministry had to distinguish between medical comforts and medical foods needed for therapeutic reasons. The Food Rationing Special Diets Advisory Committee included men who were authorities in their particular fields and had a wealth of clinical experience. This committee did not pass judgment on treatment. It was in fact an appeal board and had performed its functions well. It was true that the Ministry relied on one or two members of the committee but these men were highly qualified and it would be difficult to refer each case to every member of the committee. The proposal for regional committees would involve the setting up of seventeen more committees of busy men and she opposed the suggestion at the moment. The Ministry was considering the matter carefully however.

EPIDEMIOLOGICAL NOTES

Neonatal Diarrhoea in Derby

At Derby City Hospital 2 premature infants, five days old developed diarrhoea on Feb 20. Further infants were affected on Feb 23, 24 (2), and 26 (2), and on March 1 2, 4 (3), and 8—a total of 13 cases. There were 6 premature infants and of these 4 died and the two others were seriously ill but are recovering, 2 out of 7 full-term infants have died. Clinically there was a period of one to two days of lethargy, anorexia and loss of weight followed by the sudden onset of fever (100°–103° F 37.8°–39.4° C), and watery diarrhoea. The colour of the stools varied from cream to green, orange stools were seen but were unusual. Dehydration followed and death occurred in most cases about the fourth day. Recovery with fall of temperature and the gradual return of the stools to normal took place usually towards the end of the first week in the milder cases.

The first 4 affected infants were delivered in the same labour ward within twenty six hours on Feb 15 and 16. They were distributed to the three maternity wards and later became the first cases in each ward. Subsequent cases may well have been infected from the primary cases owing to overcrowding and lack of staff. The maternity department was dealing with about double the pre-war number of admissions. There was no case of diarrhoea among the infants in the preceding six weeks. None of the affected infants had been wholly breast-fed. The onset in 4 cases followed the institution of artificial feeding breast-feeding having failed. No mother appears to have been affected. One nurse did suffer from diarrhoea, but on clinical grounds it seemed unlikely that she had any connexion with the outbreak. The steps taken to check the outbreak included closing the affected ward to new admissions, the discharge of healthy mothers and infants as soon as possible, the isolation of all proven and suspected cases, spacing the remaining healthy patients as widely as possible and vigorous overhaul of nursing technique with emphasis on the importance of breast-feeding without supplement.

Since March 9 one infant affected on Feb 24 has died and there have been 2 further return cases, one fatal. It seems probable that a few more cases will appear before the outbreak is finally controlled.

Discussion of Table

In England and Wales an increase was recorded in the notifications of scarlet fever 86 and whooping-cough 63 with a decrease in the incidence of measles 2,428, acute pneumonia 158 and diphtheria 31.

The changes in the local trends of scarlet fever and whooping-cough were small and no large variations occurred. A small decrease in the incidence of diphtheria was recorded throughout the country, 28% of all cases were notified in Lancashire.

The fall in cases of measles was mainly confined to the northern sections. The largest variations in the local returns were decreases in Lancashire 789, Warwickshire 371, Yorkshire West Riding 208, Middlesex 196, Northumberland 154, and Durham 133. There were increases in Surrey 106, Essex 101, and Southampton 86.

No further cases were reported from the outbreak of dysentery in Hertfordshire St Albans RD. Two new outbreaks were reported during the week, Middlesex, Southall MB 13 and Suffolk, Newmarket UD 10.

The one case of smallpox diagnosed in Stepney, London is linked to the outbreak in Grimsby, where 14 cases with 6 deaths have been reported.

In Scotland no further cases of dysentery were reported from Banff county, and the notifications for the whole country dropped to 16. With the exception of measles which fell by 45, the notifications of other diseases underwent little change.

In Eire the incidence of whooping cough declined by 22, but a fresh outbreak with 16 cases was notified in Westmeath, Coole RD. Notifications of diarrhoea and enteritis increased by 20.

In Northern Ireland the outbreak of measles in Belfast CB continued to decline, and 194 cases were notified during the week, a fall of 93.

Week Ending March 8

The notifications of infectious diseases in England and Wales during the week included scarlet fever 1217, whooping cough 2,461, diphtheria 182, measles 12,137, acute pneumonia 958, cerebrospinal fever 86, dysentery 69, acute poliomyelitis 10, smallpox 7, paratyphoid 4, typhoid 4. Deaths from influenza in the 126 great towns numbered 92.

Births and Deaths in Eire

The following table shows the figures for the 13 principal towns in Eire each week from the week ended Oct 26, 1946, to the week ended Feb 22 1947. During this period there were no deaths due to dysentery, scarlet fever, smallpox, or typhus.

Week ended	Births	Deaths		Deaths Caused by					
		All Ages	Under 1 Year	Diphtheria	Diarrhoea and Enteritis (Under 2 Years)	Meningitis	Influenza	Typhoid Fever	Whooping cough

Births and Deaths in the United States

The provisional report for 1946 puts the birth rate at 23.3 per 1,000, which is 8% higher than the wartime peak of 1943. The birth rate in 1943 was the highest recorded since 1924. The infant mortality was 36.1 per 1,000 live births, and was 1.4 below the rate for 1945. The general death rate was 10.1 per 1,000 compared with 10.6 in 1945.

Medical News

Lord Horder, who is Chairman of the Standing Committee on Nutrition of the Food and Agriculture Organization of the United Nations, left for Washington on March 15 and will be away until April 14.

A Clinico Pathological Meeting of the West London Medico-Chirurgical Society will be held at the West London Hospital to-day (Friday, March 21) at 8.45 p.m.

Dr J. A. V. Butler will deliver the last of his three Cantor Lectures on "Enzymes: Their Isolation, Structure, Mode of Action, and Place in Nature" before the Royal Society of Arts (John Adam Street, Adelphi, W.C.) on Monday, March 24, at 5 p.m. The first two lectures were given on March 10 and 17, and all three will appear in the Society's *Journal* in due course.

A meeting of the Nutrition Panel of the Society of Chemical Industry will be held at the Chemical Society's rooms (Burlington House, Piccadilly, W.) on Wednesday, March 26, at 6.30 p.m., when Dr Kenneth Mellanby will read a paper on "Human Water Requirements." A discussion will follow. All members of the Food Group are invited to attend the meeting.

A meeting of the Medico Legal Society will be held at 26, Portland Place, W., on Thursday, March 27, at 8.15 p.m., when a paper by Drs Charles E. Newman and Ronald H. Graveson on "The Education and Status of the Medical and Legal Professions" will be read.

The annual meeting of the Mental After Care Association will be held at Burlington House, Piccadilly, W., on Thursday, March 27, at 3 p.m., when Dr Henry Yellowlees and others will speak on the work of the association. All interested are invited to attend the meeting.

The first course for resettling Polish pharmacists under the Bill sponsored by the Government has opened at the Brighton School of Pharmacy. About sixty of those who can pass an examination like the one for foreign pharmacists under the Defence Regulations are to be temporarily registered here.

The Harveian Society of London announces that the Buckston Browne Prize for 1946 has been awarded to Michael Kelly, M.D., University of Melbourne, for his essay on "The Pathology and Treatment of Fibrositis."

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Diphtheria Immunization

Q—Should diphtheria immunization in children be repeated in all cases after five years?

A—If a child receives its first course of artificial immunization at the age of 9 months to 1 year the resulting immunity will begin to wane after a few months, and two years later may have fallen to a very low level. Such a child, if exposed to the risk of infection may develop diphtheria which will not usually be severe since the diphtheria toxin will stimulate the sensitized antibody-producing cells into activity and in a few days' time enough antitoxin will have been formed to neutralize the toxin. The usual practice in this country is to give a child its first boosting dose at 5 years of age when it goes to school, but in an area where diphtheria is still prevalent it might be wiser to give this dose at 3 years of age. The effect of the boosting dose is to raise the antibodies to a high level and as a rule the fall in antibody titre takes place much more slowly than it does after the first immunization. Further, when the child goes to school and mixes freely with other children it may be exposed to small doses of diphtheria bacilli, which will help to maintain immunity. Alternatively the child may be given a second boosting dose of diphtheria prophylactic around the age of 10 years.

Diphtheritic Tonsillitis

Q—Should cases of diphtheritic tonsillitis be treated as diphtheria in infectious diseases hospitals or should they be treated at home as tonsillitis as their clinical course is invariably mild?

A—Throat infection with *C. diphtheriae* in those who have been artificially immunized or have acquired some natural immunity often presents a clinical picture of follicular tonsillitis with a patchy exudate that can easily be wiped off, and a more acute inflammatory reaction with a higher temperature than is usual with typical faucial diphtheria. As a rule these patients have little or no toxæmia, and the infection may be called diphtheritic tonsillitis. It is almost invariably associated with either *gravis* or *intermedius* types of *C. diphtheriae* which have a greater capacity for tissue invasion than has the *mitis* type and may therefore produce a local throat infection in those who have some antitoxic immunity. Although the clinical course is usually mild, post-diphtheritic paralysis does sometimes occur, and in the more severe infections antitoxin should certainly be given. However, the important point is that the patients are a potential danger to family or other close contacts and should therefore be isolated at home if the conditions are suitable, or, if not, in hospital. Practitioners should keep a sharp look out for this type of infection and obtain a bacteriological diagnosis whenever possible.

Diphtheria Treatment without Antitoxins

Q—Supposing that diphtheria antitoxin were not available how should one treat a case of diphtheria?

A—It is difficult to visualize circumstances where diphtheria antitoxin will not be available for the treatment of diphtheria. If the questioner has in mind an island or some outlandish place far from a hospital, the answer surely is that the prudent doctor will always carry antitoxin with him. Antitoxin is available free from the medical officer of health and kept even at room temperature retains most of its potency for some months. Moreover, the present refined enzyme digested antitoxin is so concentrated that an adequate dose for an early case may be contained in 1 to 2 ml, while the risk of serum reaction or anaphylaxis is minimal. There is no alternative treatment to antitoxin, although many patients with mild or moderate infections will doubtless recover without it, as happened in the pre antitoxin days. Penicillin or other chemotherapeutic drugs may

LIVOGEN

Trade Mark

The recent cancellation of the Liver Extract (Regulation of Use) Order, 1945 (b), makes it possible for Livogen once again to be prescribed freely and without restrictions upon its use

Livogen is accordingly now available, it is made to the same formula as that used until 1941 which includes, in addition to fifty per cent of liquid extract of liver B.P., extract of yeast, vitamin B₁ and nicotinic acid

Livogen is of remarkable value in the treatment of anæmias, in the prevention of polyneuritis induced by gastric abnormalities and of the polyneuritis of pregnancy and alcoholism, also in constipation, in anorexia and in retarded growth. Livogen is prescribed also in the various degrees of lassitude and debility characteristic of convalescence, dietary inadequacy and following periods of physical or mental stress

Details of dosage and other relevant information are available on request and supplies of Livogen can be obtained from the principal retail pharmacists

GOLD THERAPY

GOLD therapy now takes a foremost place in the treatment of rheumatoid arthritis. Toxicity, formerly of sufficient severity to detract from its general usage, has been materially reduced by a more careful selection and management of cases, a much lower scale of dosage, and the development of less toxic gold salts. Crookes Auro Calcium, a finely divided aqueous suspension of calcium aurothiomate, provides an appreciable contribution to this reduction of toxic effects.

efficient, low-dosage treatment of ulcerative colitis with

Sulfathalidine

Phthalylsulphathiazole

This nontoxic low dosage enteric sulphonamide is exceptionally effective against acute and chronic ulcerative colitis and recently proved successful in the treatment of 76 out of 80 patients with this disease. After therapy with the drug stools become formed and odourless, blood in stools disappears, cramping in abdomen subsides within 48 hours and excretions are reduced substantially.

SULFATHALIDINE (phthalylsulphathiazole) is indicated also in the treatment of regional ileitis, as a supplement to the therapy of amebiasis, giardiasis and piratyphoid infections and as an adjunct to intestinal surgery.

SULFATHALIDINE (phthalylsulphathiazole) maintains a high bacteriostatic concentration in the gastrointestinal tract (1250 mg. per cent). An average of only 5% of the drug is absorbed from the bowel and this is rapidly excreted by the kidneys. Administered in daily doses of only 0.05 Gm. to 0.1 Gm. per kilogram of body weight. Supplied in 0.5 Gm. compressed tablets in bottles of 100, 500 and 1000. Sharp & Dohme Limited, Heddington, Herts.

Vitamin Therapy *- its uses and limitations*

SUB-OPTIMAL NUTRITION

is known to be responsible for a variety of minor disorders which occur in the earlier stages of nutritive failure—for example, easy fatigability, both mental and physical, functional digestive disorders with anorexia and gastro-intestinal atony, anaemia, emotional instability, neuritic pains and lowered metabolic rate. It is now generally agreed that such combinations of symptoms are seldom attributable to lack of a single factor and that the whole vitamin B complex is needed for treatment.

CHLOROFORM

SIR JAMES YOUNG SIMPSON

OUR association with the manufacture of Chloroform dates back to 1847, when Sir James Young Simpson demonstrated its anaesthetic properties and approached Dr Thomas Smith (Founder of our Firm) with a view to obtaining sufficient quantities to carry out his pioneer work.

Our long experience enables us to produce an anaesthetic chloroform of standard composition, UNSURPASSED FOR RELIABILITY, and answering the tests of all pharmacopoeias.

destroy the organism but will not neutralize toxin that has already been produced. If diphtheria were an acute infection that could be diagnosed easily within twenty-four hours of onset penicillin therapy might be considered as a substitute for antitoxin, but unfortunately diphtheria is too often an insidious disease and a considerable amount of toxin has been formed, with damage to vital tissues, before the infection is diagnosed.

Sex Predetermination

Q—I saw recently a report that a programme of research could be laid down which over a short period of years would allow sex to be predetermined. Is it possible to indicate briefly what work is being pursued, what would be the type of research still to be undertaken, and what are the most recent authoritative papers on this subject?

A—There are two kinds of spermatozoa, distinguished one from the other in respect of their sex-chromosome content. One is male determining and the other female determining. To predetermine the sex of the child about to be conceived will therefore become possible when the two different kinds of spermatozoa can be separated one from the other in the ejaculate, that part containing one or the other kind being introduced into the female about the time of ovulation by the techniques of artificial insemination. Recent experimental work in this field has taken the form of so altering the chemical atmosphere of the vagina of the female by the application of lactic acid or, alternatively, of sodium bicarbonate that one form of spermatozoa is advantaged in its journeying towards the ovum. The results of such experimental work are not convincing, but the methods employed indicate the kind of investigations that need to be undertaken.

It is eminently possible that a team of biologists, biophysicists and biochemists adequate in numbers, interest, and knowledge could within a reasonable time elaborate techniques which would disclose knowledge yielding the power necessary for the separation of the two forms of spermatozoa. Such power could certainly be used with great advantage in the agricultural field—in the dairy industry, for example. In the case of the human subject any biological invention endows a human society with knowledge which in application can yield either human amelioration or distress and degradation. The power to predetermine sex in this way, misused by the irresponsible or by the tyrant, could seriously disturb the terrestrial destiny of mankind. The subject is extensively reviewed in the new edition of F. H. A. Marshall's *Physiology of Reproduction* which is shortly to be published. (See also *Journal*, Aug. 10, 1946, p. 216.)

Sensitivity to Hair Dyes

Q—A patient of mine had dermatitis of the scalp thought to be due to the application of a hair dye. Does this happen often? What factor in hair dyes is responsible and what is the usual character of the dermatitis? In this case there was severe oedema and desquamation.

A—Certain types of hair dyes generally contain para- or meta-phenylenediamine, or both, or some allied chemical. There is probably an incidence in the general population of idiosyncrasy towards such chemicals of about 4%. Such individuals may react to a first application of the dye by an acute contact dermatitis with redness and oedema, sometimes weeping, and scaling and scabbing of the head and face. This may extend further by direct spread or from absorption through the blood stream. Other individuals may develop sensitivity after a number of applications. Tests to ascertain whether the patient is sensitive or not are not very satisfactory, and reactions may not occur for twenty-four days or longer after the tests. The response to treatment is naturally variable, depending on the patient, on the circumstances, and on possible complications.

R. M. B. MacKenna (*Journal* 1930, 1, 899) discusses para-phenylenediamine dyes and he suggests that on oxidation they give rise to quinone diimine and water, Bandowsky's base, which has caused dermatitis in people wearing furs dyed with it, is a substituted quinone diimine. MacKenna describes the toxic effects of para-phenylenediamine as being local and general. Locally there may be acute erythematous dermatitis of the scalp, face, and neck, with oedema. There may also

be headache, nausea, vomiting, diarrhoea, fever, and in acute cases albuminuria. Other easily consulted papers are by Percival (*Lancet* 1931, 2, 417), H. W. Nott (*Journal* 1924, 1, 421), A. Gautier (*Ibid.* 1909, 2, 812) and W. J. Close (*Austral Med J.* 1932, 1, 53). Generally speaking some persons are susceptible to the toxic action while others, the large majority, are not. Susceptible cases are likely to suffer mildly or severely, though severe reactions are of course much rarer than mild ones.

Housewife's Dermatitis

Q—Many housewives' hands show signs of dermatitis with dryness and hardness of the palms and a tendency to fissuring of the skin at the nail margins. It is useless to tell these women to keep their hands out of soap and water and rubber gloves are in short supply. I have tried lanolin and glycerin as local applications but without much success. Is there any better treatment?

A—It is essential to impress upon patients that the control of household dermatitis depends ultimately upon their co-operation in the matter of avoiding contact with wet alkaline irritants. When immersion is unavoidable, care should be taken to rinse the alkali from the hands to dry them thoroughly, and to dress with one of the following emollients.

R	Eucerin	oz (15 g)
	Aq. rosac	ad 3j (28.3 g)
	Et. crem	
R	Calamin	gr xl (2.7 g)
	Lanolin	gr xxx (2 g)
	Ol. oliv	oz (15 g)
	Paraff. moll	ad 3j (28.3 g)
	Et. crem	
R	Acid. borac	gr xx (1.3 g)
	Acid. salicyl	gr x (0.65 g)
	Zinc oxid	} aa gr lx (4 g)
	Amylum	
	Paraff. moll	ad 3j (28.3 g)
	Et. crem	

It is necessary first to clear the dermatitis, and for this fractional doses of rays, Lassus's paste (with or without tar), and sedative-tonic measures internally should be employed. Sometimes creams with unsaturated fatty acids (e.g., linoleic) are helpful. It must be stressed that most of these patients are eczema-prone and that a disturbance of physical or nervous health is present and requires attention. Rubber gloves, if obtainable, are sometimes troublesome to such patients, but if the dermatitis has been cleared appropriate barrier creams may help in protecting the hands from household irritants. It should be noted that household dermatitis affects chiefly the backs of the fingers and hands and finger clefts. The palms are more often affected in constitutional eczema.

Pregnanediol Test for Pregnancy

Q—What is the technique of the pregnanediol excretion test for pregnancy and threatened abortion?

A—The pregnanediol test for pregnancy is based on the fact that this excretion product of progesterone appears in the urine in greater quantities during pregnancy than in most other circumstances. Threatened abortion is presumably sometimes due to a progesterone deficiency, and a low excretion level of pregnanediol in such cases is therefore an indication for progesterone therapy, whereas if the excretion is up to average another cause for the abortion should be sought. A gravimetric method of assay of pregnanediol which is extracted from the urine in the form of sodium pregnanediol glucuronidate was described by Venning (*J. Biol. Chem.* 1937, 119, 473) and has been used by many workers, including Hain and Robertson (*Lancet* 1939, 1, 1324) in this country, as a means of diagnosing pregnancy. The references should be consulted for details of the method, which is complicated and laborious, requiring a litre of a twenty-four-hour specimen of urine and taking three days to complete. A few years later Guterman (*J. Clin. Endocrinol.* 1944, 4, 262, 1945, 5, 407) described the test which bears his name. It is carried out on 100 ml of a first morning specimen of urine, and after a more simple

extraction process a rough assay of the pregnanediol content is made by noting the colour which develops on the addition of concentrated sulphuric acid. It is economical and requires only three hours to complete, but it is less accurate and reliable and is suitable only for crude quantitative work unless a spectrophotometer is employed. The technical details are to be found in Guterman's papers and in a recent article by McCormack (*Amer J Obstet Gynec* 1946, 51, 722). The special value of the test in cases of threatened abortion is dealt with by Guterman (*J Amer med Ass* 1946, 131, 378).

Lymphoedema of the Legs

Q—A woman aged 38 has a history of swollen legs since she was 15. The oedema pits and the left leg is worse than the right. A sister has had a similar complaint since the same age but three other sisters are normal. Does this rule out Milroy's disease and if so what is the cause of this condition?

Q—A young woman of 25 has swollen legs which pit only slightly. None of the usual causes of oedema can be elicited and correction of pes planus has not been effective. Can you suggest diagnosis, prognosis and treatment?

Q—A young woman aged 32 complains of intermittent swelling in the ankles affecting the anterior aspect of the joints which began four years ago. It is worse on the right side and is accompanied by a dull ache relieved by resting. Some subcutaneous thickening is present. Urine, heart and veins are normal. She has carried out foot exercises but with out result. Suggestions as to cause and treatment would be welcomed.

A—All these are cases of lymphoedema due to thrombosis of the lymphatics—probably the result of an infective lymphangitis which in most cases, but not in all, passes unnoticed by the patient. Tinea of the toe clefts is blamed by some, and this should always be looked for and treated thoroughly. The disease is 99% a female one, and this is held by some to be in line with the greater incidence of venous thrombosis in the female, by others it is attributed to the difference in the clothing protection of the legs in the two sexes. A few cases are due to pelvic disease, and this should be looked for in every case. The prognosis is very variable. The worst cases go on to elephantiasis; in the mildest the oedema remains a minor nuisance and confined to one leg. The treatment in all cases is the same—sleeping on an inclined bed to drain the legs at night and wearing by day a support adequate to control the oedema. In very advanced cases operations of the Kondoleon type are indicated.

INCOME TAX

All inquiries will receive an authoritative reply but only a selection can be published.

Schedule E Liability—Expenses

G receives a mileage allowance for the use of a car which is essential for his work. The allowance is considered insufficient for the partial use of the car for such purposes. Can he claim for the excess? The maid who is kept for domestic reasons often takes telephone calls arising from his work, can anything be claimed for the cost of the maid?

* **G** can claim for the excess of the cost over the mileage allowance, and in doing so can include depreciation allowances or the cost of renewal of the car. It should be understood, however, that it is only the necessary cost that is allowable—or rather the proportion of that cost as compared with the total private and official use of the car—and that where a special expenditure such as a renewal of the car is incurred, the Revenue may contend that it should be spread over, say, three or four years.

As regards the telephone calls, the circumstances seem to be such that the proportion of the maid's time spent in answering calls is so small as to render such a claim valueless.

There is no publication giving general advice to medical men which is now available.

Examination Fees

J E inquires whether any relief can be claimed for examination fees.

* **No**. They are in the nature of capital outlay, and are not regarded as expenses incurred in carrying out the duties of an appointment.

Letters and Notes

Nocturnal Diuresis

Dr N J W THOMPSON (St Helens) writes. I read with interest the letters from **Dr B E Read** (Jan 25, p 168) and **Dr S D Sturton** (Feb 15, p 283) on the subject of nocturnal diuresis among prisoners of war and internees in the Far East. I was a prisoner of war in Nagasaki, No 14 Camp, where also nocturnal frequency was a very common complaint.

I am not prepared to surmise as to how much the condition was due to a rice diet *per se* or to nervous strain, but in my opinion an important causative factor was a large fluid intake in the diet. The latter consisted mainly of a cereal (rice, barley, and millet). The cereal was cooked by soaking in water and steaming. During this process, it swelled to more than three times its original bulk, so that it contained at least 70% water. In addition a bowl of soup was provided consisting almost entirely of coloured water. After consuming the above evening meal most of the men still felt the pains of hunger. To alleviate this and contrary to medical advice, they were in the habit of drinking large quantities of tepid water under the impression that by filling up with something they would feel better. I estimate that many had a fluid intake of more than 3 to 4 pints (1.7-2.3 litres) after 7 p.m. It is little wonder that they had nocturnal frequency.

Dermatitis Herpetiformis

Dr R MILTON (Haslemere) writes. Referring to the inquiry under 'Any Questions?' (Feb 15, p 281) on the treatment of dermatitis herpetiformis, your correspondent may care to try 'benadryl' capsules. One recent case (male aged 62), previously controlled by arsenic suffered a relapse after withdrawal of this drug due to hyperkeratosis and colitis. This relapse was adequately cleared up by the use of 'benadryl' capsules 50 mg, 1 t.d.s. This dose had to be reduced to one capsule twice daily owing to tiredness. He has been nearly free of symptoms and has continued the drug for the past five or six months. It would seem therefore that 'benadryl' is purely symptomatic in its effect, and I would like to know what contraindications there are for its continued use.

Dr T H K MacLAUGHLIN (Leicester) writes. Having suffered from this distressing complaint myself may I suggest that before resorting to any severe treatment the following be given a trial:

- (1) Ung atropinae B.P.C. 1 dr (4 g) Ung glycerin plumb subacet 1 oz (30 g)
- (2) Tab phenobarb 1 gr (65 mg) unam nocte

This was the only treatment which afforded me any relief over 20 years ago, and I have had no recurrence.

Treatment of Post operative Thrombophlebitis

Mr HAROLD DODD (London W) writes. May I suggest another treatment alternative to that recommended in 'Any Questions?' (Feb 8, p 243)? It is: (1) The early ligation and division of the femoral vein above the thrombosis with injection of a carbolic acid sclerosant into the lower segment. (2) The administration of dicoumarol orally. (3) Getting patients up for toilet, meals, and bed making. (4) The application of pads of wool and elastic bandages from the toes to the groins. If after this there is still pain then more wool and another bandage is put on over these. A further part of the remedy is that of prevention as by placing a pillow under the patient's knees during the operation, this raises the calves off the hard table, the pressure of which encourages thrombosis in the veins of the posterior tibial muscles. Shortly after recovery from the anaesthetic patients are sat up with the legs over the side of the bed and 24 hours later they sit out of bed on to a hard chair morning and evening. The practice of treatment in bed for 4-8 weeks for phlebitis can safely be superseded by firm bandaging, getting about, and doing their lighter usual duties. Septic foci, especially apical dental sepsis and cholecystitis are always watched for in phlebitis and before operations.

MARROW BIOPSY

PREPARATION AND USE OF PARAFFIN SECTIONS FROM STERNAL-PUNCTURE MATERIAL

BY

D F CAPPELL, MD H E HUTCHISON, MB

AND

G HARVEY SMITH, MB

(From the Pathology Departments of the Western Infirmary Glasgow and Royal Infirmary, Dundee)

[WITH PHOTOGRAVURE PLATE]

The value of sternal puncture as a diagnostic measure in disorders of the haemopoietic system is now widely accepted by haematologists, and the procedure is generally recognized as being safe and causing little or no discomfort to the patient. The usual method of dealing with the biopsy material consists in the microscopical examination of marrow smears stained by one of the Romanowsky stains, a differential count of the nucleated cells, and an estimation of the leucocytogenic-erythrocytic ratio. Other workers carry out total nucleated cell counts, and supravital preparations may be made if desired. These procedures, while of great value cytologically, do not always give a true picture of the marrow as a whole and give no indication of its architectural arrangement. A simple method of preparing good histological sections from sternal-biopsy marrow would be of great service and the sections would yield valuable additional information about the architecture of the marrow, especially in cases of hypoplasia or aplasia which may be difficult to assess from the smears alone. Many pathologists and clinical haematologists to whom we have shown our preparations have expressed surprise that such valuable information can be obtained so simply, since the technique for preparing satisfactory marrow sections from sternal-puncture material does not appear to be widely practised, this paper purposes to give a short account of the method adopted, after many trials, in our laboratories.

Method

After adequate local anaesthesia has been obtained and with due aseptic precautions marrow is aspirated from the sternum through a needle of the Salah type into a 10 ml. Record or all glass syringe which must have a tightly fitting piston. Sterile saline should be applied when the marrow cavity is entered in order to aspirate actual fragments of the tissue and to avoid undue admixture with blood which tends to spoil the films. No more than 5-10 ml. need be aspirated. Two or three dozen or more thin films are made by spreading a minute drop of the marrow on microscope slides without attempting to select marrow fragments and the remainder of the marrow is ejected into a 500 ml. Erlenmeyer flask containing the modified Zenker formol which we have found to give the best results. This is prepared immediately before use according to the following formula:

Zenker's fluid (minus acetic acid)	45 ml
40% formaldehyde solution	5 ml
Formol saline 10%	50 ml

Fixation is adequate in 20 to 30 minutes, and the marrow fragments must not be left for more than 30 minutes in the fixative, otherwise too much shrinkage will occur and subsequent staining will be poor. We have experimented with numerous fixatives and varied the length of fixation, but the best results were

obtained by the use of this half-strength Zenker-formol solution. When the marrow has been in the fixative for the above time 400 ml. of distilled water is added and thoroughly mixed, the tiny marrow fragments quickly settle to the bottom of the flask. The supernatant fluid is then siphoned off without loss of marrow fragments, using a Pasteur pipette with upturned point and a water pump. When the fixative is diluted the blood proteins precipitated remain as a flocculent suspension and are removed in the supernatant fluid. A further 100 ml. of distilled water is then added to the flask which is now agitated gently a few times and allowed to stand until the marrow fragments have again settled to the bottom, the supernatant fluid is then siphoned off. A final washing in distilled water is carried out, and after standing for about 10 minutes the water is siphoned off and 100 ml. of 60% spirit is added.

The marrow should not be left for more than 15 minutes in 60% spirit, as maceration will occur, but this step is useful as it allows practically all of the protein precipitate to be discarded and only marrow fragments should now remain. The next step is to pass the material through a series of graded alcohols in the same way—that is siphon off the supernatant fluid and add 20 ml. of the appropriate strength, 70% spirit for 15 minutes, followed by 80% then 96% for 15 minutes each before final dehydration in absolute alcohol two changes for 15 minutes each. The absolute alcohol is replaced by toluol and left for 10 to 20 minutes until cleared, the fragments are then transferred by a pipette to a small widely conical vessel with a flat bottom. The toluol is pipetted off replaced by molten paraffin wax (melting-point 54°C) and the vessel is then put in the paraffin oven for 2 hours, the molten paraffin wax being changed twice during this time. The marrow fragments, after the final change of paraffin, are allowed to settle by gravity and so gather into the small base, consequently if the wax is now hardened *in situ* the block for the microtome has the important material within a small compass. For occasional use a 2-inch (5 cm) porcelain or silica crucible may suffice but difficulty may be experienced in removing the paraffin block. Usually the block is removed from the vessel by running a hot knife round the edge and then tapping the crucible smartly on the bench. It must not be heated to melt the paraffin, as the marrow fragments lie directly on the flat base and are easily spoiled by overheating. For regular use we have found it convenient to employ a brass crucible with a detachable apex so that by unscrewing the apex the block is exposed and may be easily removed. The marrow fragments lie close to the paraffin surface and are ready for immediate cutting, trimming of the block should be avoided in case the minute fragments are lost.

At the 70% spirit stage the specimen may be safely kept for a day or two, and, in fact, may be sent to a laboratory by post if the necessary apparatus for embedding and sectioning is not available. For economy the alcohols are used repeatedly by filtering back into stock bottles through fine filter-paper to remove any marrow fragments.

Sections are stained by the ordinary methods such as haematoxylin and eosin for rapid reports, but a more detailed

study of the marrow is made on sections stained by Maximow's eosin-azure method or by one of the Romanowsky methods. Special stains can, of course, be used for example we have found Mallory's aniline-blue method of value in the recognition of Gaucher cells in sternal marrow. Microchemical tests for the presence of iron can be applied. Zenker-formol fixative does not prevent the application of the prussian-blue method if brief treatment with warm hydrochloric acid is used (Mallory).

Excellent histological preparations of marrow are obtained which show the general architecture, the proportion of fat and cellular tissue, and the relationship of leucopoietic and erythropoietic tissue to one another and to the supporting framework. The number and disposition of the megakaryocytes are readily assessed, and the presence of abnormal elements is more easily detected than in the smear preparations. We have found that unless large numbers of smears are examined a true impression of the marrow may not be obtained, especially in regard to the megakaryocytes, which are not usually evenly dispersed. Abnormal elements, such as myeloma cells, Gaucher cells, and possibly tumour cells, may be recognized in the sections, and confusion due to admixture of blood does not arise. In a case of aplastic anaemia the marrow sections remove all doubt as to whether the lack of haemopoietic elements in smears is due to failure to obtain a true sample of the marrow. These points are illustrated in the accompanying photomicrographs (see Plate).

Summary

For the interpretation of alterations in bone marrow architecture the value of histological sections is emphasized as a supplement to the usual smear technique. A simple method is described for the preparation of paraffin sections from sternal-puncture biopsy performed with the ordinary type of needle. Representative photomicrographs illustrate the results obtained.

PAROTIDECTOMY: INDICATIONS AND RESULTS

BY

HAMILTON BAILEY, FRCS Eng, FACS, FICS
FRSE

Surgeon Royal Northern Hospital London General Surgeon,
Metropolitan Ear Nose and Throat Hospital

[WITH PHOTOGRAVURE PLATE]

To most general practitioners and to many surgeons, the mere mention of complete parotidectomy (Fig 1, Special Plate) conjures up an apparition with a hideous facial deformity. Superficial lobectomy (Fig 2, Special Plate) is a far more desirable term than subtotal parotidectomy, but until it is generally conceded that the anatomical classics are inaccurate in their description of the facial nerve—that the facial nerve does not plunge into the main body of the gland and there divide within the parenchyma—the term lobectomy in connexion with the parotid gland is meaningless. To clear up misunderstandings concerning the relationship of the facial nerve, to beg contemporary anatomists to revise their teaching and alter their textbooks in this respect, is only one of the tasks that I have set myself. It is my ambition to dispel deep-rooted beliefs concerning parotid tumours, beliefs almost amounting to old wives' tales.

The Bogy of Facial Palsy

"Leave it alone! If you have it cut out you will probably get paralysis of the face." This was the advice given to the brother of one of my nursing sisters by a comparatively

young North of England practitioner, as a result, the patient adamantly refuses to submit to operation. Similar advice was given to another patient by a middle aged doctor practising on the Welsh border. I mention these examples because most of my patients come from London or the Home Counties, where advice such as this seems to be the rule. Further inquiry convinces me that this attitude

FIG A—Ages at which mixed tumours of the parotid gland first appeared (J. McFarland's statistics)

towards operation is adopted by the majority of practitioners throughout the world. Amazingly enough, the profession does not realize that it is only a matter of time before the seventh nerve becomes implicated by the tumour and that this is a far more frequent happening than facial palsy resulting from the surgeon's knife. Furthermore, when a neoplasm has advanced so far as to cause facial paralysis, it is unlikely that the tumour can be removed *in toto*.

Joseph McFarland,* who held the chair of pathology at Philadelphia, studied parotid tumours for thirty years. Unlike most pathologists, in addition to studying the macroscopical and microscopical characters of the specimens, he investigated the clinical histories of the patients. As a result he pronounced the recurrence rate to be much higher in the case of removal of small as opposed to larger tumours. Kennon, of Liverpool, substantiated this observation. Presumably as the outcome of these well-founded observations there started the pernicious practice of waiting until the tumour got larger. How large has never been stipulated, that has been left to the patient or his doctor to decide. In this connexion it is important to point out that clinically I myself have found it difficult to be sure that a given tumour is small. Some of these swellings feel definitely circumscribed and are movable on the deeper structures, yet when they are displayed to the light of day they prove to be veritable icebergs—four-fifths being

*Joseph McFarland died in September, 1945. His daughter, Dr. Helen McFarland Woodbridge, is carrying on her father's collective study of parotid tumours at the School of Dentistry, University of Pennsylvania.

beneath the surface. Again, some of my biggest specimens originated deep in the gland and consequently did not produce the largest excrescences. Therefore a pre-operative clinical photograph does not necessarily reveal the magnitude of the neoplasm.

It is generally conceded that the earlier a malignant tumour is removed, the better. Why in the world should a tumour of the parotid gland be an exception to this rule? The reason is that other misconceptions, notably the illusion of enucleation and the myth of the ugly scar, have vitiated the dictates of common sense.

The Illusion of Enucleation

"I have sometimes seen little tumours the size of peas or little pins' heads in close juxtaposition to the larger, easily recognized tumour" (McFarland). Here is one explanation of the frequency of recurrences, and a strong argument for performing subtotal or total parotidectomy in all cases of mixed parotid tumours. Important as is McFarland's observation, I am convinced that most recurrences are due to incomplete removal of the mother tumour, and my explanation accounts for the well-established fact that small tumours are followed by the early and frequent (30% or more) recurrences. Let us see how this occurs. Through a limited transverse incision the surgeon endeavours to expose the surface of the tumour. The cheek is so richly supplied with blood that, in spite of the application of numerous haemostats, the parotid gland cannot be seen clearly in the depths of the wound. The surgeon therefore largely relies on palpation to define the limits of the swelling. The incision into the gland substance having been deepened, still more bleeding is encountered, and he may or may not define the capsule of the tumour. The smaller the tumour the more likely is this step to prove unsatisfactory. The capsule is opened and an attempt is made to enucleate the tumour with the finger, in much the same manner as an adenomatous prostate gland is enucleated suprapubically. In some large and moderate sized firm, solid tumours this procedure is accomplished with a sense of satisfaction. In other cases, particularly in small friable tumours and those in which cystic degeneration has occurred, the contents of the capsule are fragmented, or a jelly-like material escapes. It should be evident that even if one cell is spilled in the wound recurrence is possible. Having "enucleated" the tumour, the surgeon who has devoted attention to surgical pathology, and knows that some tumour cells may still be adherent to the interior of the capsule, proceeds to remove the capsule. The smaller the capsule the more difficult is this procedure, especially in a bloody field. The capsule is liable to tear when traction is applied to it. Moreover, the most adherent part of the capsule is its deep aspect. Here the bugbear of injury to a branch of the seventh nerve is often the final deterrent to good intentions. I submit that malignant cells spilled during intracapsular enucleation or cells left in the interior of a portion of the capsule that has not been entirely removed, account for 90% of recurrences.

Operative Details

Operations on parotid tumours are usually undertaken through transverse incisions. 'The smaller the incision the better the cosmetic result' is an uppermost thought in the surgeon's mind. Furthermore fearing injury to the facial nerve, the surgeon likes to feel that his incision into the gland runs parallel to branches of the seventh nerve. Limited transverse incisions for removing parotid tumours should be abandoned, because it is impossible to determine what type of operation is necessary until the whole gland has been displayed, and any operation that has for its

objective complete ablation of the tumour requires full exposure of the whole gland.

The Incision Advised—The surgeon transfixes the lobule of the ear with Lane's forceps, and retracts the lobule suitably. The assistant stretches the skin of the cheek with the flat of his hand, while a J-shaped incision is made, beginning at the level of the zygomatic arch and proceeding down the side of the face as close as possible to the pinna, curving round the root of the lobule to end on the tip of the mastoid process (Fig 1, Special Plate). A large flap of skin is reflected by undercutting. If the whole parotid gland is not in view (the gland is a variable structure) the incision must be enlarged still further by extending it down the neck from the tip of the mastoid process, along the anterior border of the sternomastoid. Contrary to what may be thought this formidable incision leaves a surprisingly inconspicuous scar.

Operation—No attempt should be made to remove any parotid tumour until the whole gland is in full view. Only then or even after an extracapsular resection (Fig 3, Special Plate) has been begun, is it possible to tell how deeply the tumour plunges into the gland. Ligation of the external carotid considerably minimizes the bleeding that otherwise obscures a dissection of the branches of the seventh nerve. The temporofacial division is seen clearly once the superficial lobe has been mobilized. In extracapsular resection sufficient parotid tissue should be removed to ensure that the tumour capsule is not encroached upon. If the tumour is found to extend deeply, rather than risk cutting the branches of the facial nerve this operation should be abandoned in favour of superficial lobectomy. In all operations on parotid tumours the wound should be kept moist with 60% alcohol to shrivel up stray tumour cells that might be spilt inadvertently.

With amazement I discovered it is possible to resect large portions of the parotid gland regularly without the development of the much feared salivary fistula. In my whole series of operations, which has included 33 total or subtotal parotidectomies and about an equal number of extracapsular resections, in only one instance has a fistula resulted, and that was a tiny fistula which did not cause the patient much inconvenience. This healed within a year and remains healed.

Surgical Anatomy

There can be no doubt that surgical enterprise in the parotid region has been stultified by the instruction that surgeons have received, and are receiving, from anatomists

FIG B—For purposes of surgical anatomy the facial nerve may be likened to the meat within a parotid sandwich.

In 1938, after accidentally coming across the superficial lobe of the parotid gland in the course of an operation, and subsequently being inspired by the anatomical studies of McWhorter (1917), I endeavoured to popularize the conception that the parotid gland is a bilobed structure possessed of a large superficial and a small deep lobe connected by an isthmus. I likened the facial nerve to the meat within a parotid sandwich (Fig B).

FIG C—A comparatively early case of parotid tumour showing the typical location

In the anatomical department of the University of Chicago (1945) a medical student, L. J. McCormack, working with Dr. E. W. Cauldwell under the direction of Prof. B. J. Anson, dissected, described, and illustrated the true anatomy of the parotid gland and its relationship to the facial nerve in such a clear and convincing manner that their description is bound to become a classic. Every surgeon undertaking operations on the parotid gland should study this article.

It is, of course, possible for a neoplasm to arise in any part of the parotid gland, nevertheless, most mixed parotid tumours have their beginning in a comparatively circumscribed area—a little in front of and above the angle of the jaw (Fig C). So constant is this finding that it may be described as the typical location of this neoplasm.

The only other common starting point (and it is very much less common than the foregoing) is in the region immediately in front of the tragus. Here the differential diagnosis between an enlarged pre-auricular lymphatic gland and a mixed parotid tumour is, at the first examination, impossible unless some cause for an enlarged lymphatic gland can be discovered. When such a "gland" does not subside—or, alternatively, if it slowly becomes larger—it is wise to vote for a parotid tumour.

The Pseudocyst

"Mixed tumours are so mixed that their substance may be so soft as to lead the surgeon to suppose that he is removing a cyst" (McFarland). Because the lump feels cystic it is often assumed that the swelling is innocuous. In a few instances the advice has been given to massage the face. One can only assume that those giving this advice envisaged the swelling being caused by obstruction to a branch of the parotid tree, but the patients' histories do not indicate that sialography had been employed to support this hypothesis. True cysts of the parotid are exceedingly rare. In approximately 100 cases of non-inflammatory

swellings of the parotid gland that have passed through my hands I have encountered one example only, by sialography this was proved to be due to blocking of a large branch of the parotid tree by a stone. It should be noted that adenolymphomata (papillary cystadenoma lymphomatosum), which are cystic tumours probably arising from the lymphoid conglomerate that surrounds the first branchial cleft, are definitely benign. Such tumours are exceedingly rare, and it is quite impossible to distinguish them from degenerating mixed parotid tumours. It therefore follows that, if such a diagnosis implies that less radical treatment than that for mixed parotid tumours is indicated then unless the condition is bilateral it is dangerous to attempt to diagnose papillary cystadenoma lymphomatosum clinically.

Irrational Radiotherapy

Numbers of surgeons, I feel sure, are not cognizant of the fact that nearly all parotid tumours are completely radio-resistant. On numerous occasions I have seen patients with parotid tumours who have been steeped in the facial palsy boggy. On hearing of the proposed operation the patients have sought a second opinion—in some instances a greatly respected opinion. In all but one instance radiotherapy has been advised. Accumulated evidence has convinced me that radiotherapy is without the slightest beneficial effect on parotid tumours, except in very occasional cases that are possibly examples of adenolymphoma. McFarland followed up patients with parotid tumours treated by radiotherapy in fifteen hospitals by twenty radiologists; he was unable to find that any benefit accrued from this treatment. Janes, of Toronto, who has studied this subject, knows of no instance where a cure has been accomplished by radiotherapy, but he has observed deep, penetrating radium ulcers and intolerable pain resulting from this treatment. More such evidence is available but to bring it forward here seems superfluous.

LEGENDS TO SPECIAL PLATE

FIG 1—Low power view of the whole collection of marrow fragments from a case of hypochromic microcytic anaemia. Note the general hyperplasia of the cellular marrow, but the persistence of small fat spaces indicates that maximal cellularity has not been attained $\times 15$.

FIG 2—High power view of a megaloblastic marrow from a case of Addison's anaemia. Masses of primitive haemocytoblast cells are seen together with later nucleated red cells. There is maximal cellularity with total loss of fat $\times 800$.

FIG 3—Marrow fragment from a case of aplastic anaemia. The diagnosis from examination of the peripheral blood was uncertain between refractory megaloblastic anaemia following pregnancy and marrow aplasia. The condition proved to be completely refractory to treatment and death occurred from exhaustion following haemorrhages and sepsis $\times 330$.

FIG 4—Marrow showing clumps of Gaucher cells. The case was one of splenomegaly and anaemia with thrombocytopenic purpura in a young woman. Gaucher's disease was suspected on account of the yellowish brown pigmentation of the skin of the forehead, cheeks and conjunctivae (pingueculae), and sections of the marrow confirmed the diagnosis. Gaucher cells were not detected with certainty in the marrow smears.

FIGS 5 and 6—From an obscure case of reticulosis, apparently of the type of giant follicular lymphoblastoma. The low power view (Fig 5, $\times 50$) shows a small fragment of denser, more darkly staining cells than the surrounding marrow fragments and the high power (Fig 6, $\times 250$) shows clearly that the neoplastic tissue is replacing the marrow in foci. The marrow smears showed merely an increase in mononuclear cells but an opinion would not be given whether these cells were diffusely mingled with the marrow elements or were derived from metastatic foci of the lymphoid neoplasm.

Prognosis and Treatment of Facial Palsy

After operations upon the parotid gland that involve dissection of the seventh nerve and the free use of 60% alcohol in the wound, a major degree of facial palsy always occurs this may persist for weeks or months. In the early stages Pickerill and Pickerill's method of supporting the facial musculature by strips of adhesive plaster cannot be bettered. Later, in cases where drooping of the mouth persists, Dahlberg's internal splint, which is a dental prosthesis, is superior to the hook and chain commonly employed. In four cases where I have known that I have cut a primary division of the facial nerve, the patients, instead of haunting me as I expected, have eventually either completely recovered or recovered to such a degree that they are unaware that the nerve is not functioning fully. This was the second pleasant surprise that I experienced in my sally into this field of surgery, and it equalled my amazement at the non-development of a fistula following lobectomy.

Since studying McCormack, Cauldwell, and Anson's description of the anatomy of the facial nerve, I have verified in the living the anastomotic twigs connecting the temporo-facial and cervico-facial divisions of the seventh nerve anterior to the parotid isthmus (Fig D). I believe

FIG D—Showing the anastomotic twigs between the cervico-facial and temporo-facial divisions of the facial nerve. Note that the temporo-facial division is more than twice the size of the cervico-facial division (after McCormack, Cauldwell, and Anson).

that it is the existence of these communications that accounts for the eventual restitution of function of the seventh nerve when one of its primary divisions is known to have been severed.

Even if the main trunk of the facial nerve is cut by accident or design (and I think the former is unlikely given reasonable skill) this is not an occasion to join the melancholy band at the wailing wall. I only wish that all the tragedies of life were as remediable as facial palsy. Certainly my experience of it has been small, but I have found that in the only two examples in which I employed it Lodge's operation of inserting a strip of fascia subcutaneously is most effective. J B Brown, by suturing the free fascial grafts to the temporal muscle, claims to mobilize as well as to rectify the drooping of the face. Sheehan's method of utilizing tantalum wire subcutaneously is reported to give results equal to those obtainable by fascial grafting. I repeat that such operations as these are necessary only when the main trunk of the facial nerve has been cut. In my experience this should be a most exceptional occurrence indeed if Janes's excellent suggestion is followed and the greater part of the mastoid process is temporarily resected in order to give access to the stylomastoid foramen, the main trunk of the facial nerve can often be found early in the course of the dissection even when the tumour is wedged between the mandible and the skull.

Perhaps what is more to be feared, when nerves in and around the parotid salivary gland have been damaged, is

not the muscular palsy but the much less-known auriculo-temporal (Frey's) syndrome. In Frey's syndrome when the patient eats the cheek becomes red, hot, and painful, and beads of perspiration appear upon it. There is also hyperaesthesia of the face, especially during shaving.

Conclusion

As an experienced teacher I am convinced that in the whole realm of clinical surgery there is not a condition that approaches mixed parotid tumours for misconceptions. Here is a neoplasm that remains supremely curable for years, sometimes for a decade or more. Yet because of misconceptions concerning its behaviour and its treatment it is allowed to pass from curability to incurable malignancy. Worse still, while it is yet small and encapsulated, malignant cells, previously locked up by Nature, are let loose by surgical interference (a revolting term beloved of bygone physicians, which in this instance may be used to some purpose).

If these misconceptions can be swept aside and if general surgeons will devote even one-quarter of the time and attention to parotidectomy that they have expended in acquiring the skill to perform such operations as oesophagectomy and total gastrectomy, I believe that Cinderella Tumor Mistus Parotidis, an unadopted child of ultra-surgical specialization, will take her rightful place in a category where our conception of surgical pathology tells us she belongs—absolute curability.

At the Fourth Annual Conference of the American Group Therapy Association, held on Jan 10-11, Dr George E Gardner co-director of the Judge Baker Guidance Centre of Boston, suggesting that child guidance clinics in the future would employ treatment groups extensively for young children and their parents said that the children's group permitted expression of drives in a setting with flexible but definite limitations, where support for ego growth and development was supplied as well as sympathetic and impartial dealing with the children. In the parents' group the therapist served as a catalytic agent in the discussions. She gave authoritative opinions when requested, controlled the outpouring of emotionally charged material, and helped relieve guilt and anxiety in the group members. Both therapists kept in the background except when situations arose that demanded intervention. Dr Hyman Spotnitz, of the Jewish Board of Guardians found that through the analysis of the group interviews two trends or forces could be discerned, the reproductive constellation of forces and the inadequacy constellation of forces. These were in constant opposition. The drive to become parents, and better parents than their own was in opposition to the girls' feelings of inadequacy to achieve these aims. When the former constellation was ascendant the girls were functioning harmoniously as a group when the inadequacy constellation was ascendant the drives became disruptive and tended to break up the group.

A PLEA FOR LATERAL ORBITOTOMY (KRONLEIN'S OPERATION)

BY

H B STALLARD, MD, FRCS

Eye Surgeon St Bartholomew's Hospital

[WITH PHOTOGRAPHIC PLATE]

There has been of late a trend to advise exploration of all orbital tumours through the transfrontal route. Such an operation is of course in the province of the neurosurgeon. Perhaps one reason for this is the statement of so eminent a neurosurgeon as W E Dandy (1943) that in his experience in 75 to 80% of cases both the orbit and the cranial cavity are involved in a neoplasm which causes unilateral proptosis. Another reason is the reluctance and timidity of some eye surgeons to undertake the surgical approach through the lateral wall of the orbit (lateral orbitotomy—Kronlein's operation)—a route in my opinion fully justifiable, and one to be preferred to the transfrontal approach in the case of a neoplasm the physical signs of which show to be entirely within the orbital cavity. Increasing hyperopia may well be diagnostic of a tumour limited to the orbit. Good stereoscopic radiographs of the orbital walls and optic foramina and canals are helpful in excluding extraorbital extension.

Dandy made the following comment about orbital tumours: "As a matter of fact it is rarely possible before operation to be certain whether or not the tumour also lies within the cranial chamber as so many of them do." Harvey Jackson (1945) cannot agree with this statement, and he writes: "In fact my experience is that by careful clinical examination, by judicious radiography and by suitable application of laboratory investigation, not only is the diagnosis of tumour to be reached, but its ramifications regularly revealed and not infrequently its pathological nature surmised." Nevertheless, in discussing treatment he writes: "My opinion concurs absolutely with that of Dr Dandy in that the transfrontal route is preferable in every way. Through a frontal osteoplastic flap a more direct and more adequate exposure is obtainable, any extension intra-cranially is approachable, less interference with ocular motility ensues, and there remains no visible and ugly scar. As for the replacement of a prominent eye by one that in addition pulsates, this is untrue."

I think a more direct and more adequate exposure is obtained by lateral orbitotomy in cases where it is known that the neoplasm is limited to the orbit. The suggestion that after lateral orbitotomy the patient has an ugly scar is untrue. By suturing the incision carefully in two layers, by using for the skin a plastic hook, No. 4 eye atraumatic needles, with 00 black silk, and by placing the sutures 3 mm apart and 2 mm from the edges of the incision, the scar is reduced to a thin line which is not obvious.

The case report given below illustrates failure to remove an orbital tumour by the transfrontal route in July, 1945, and its successful excision through the lateral orbital approach in February, 1946. Incidentally Maurice Drell (1944) also reports a case in which the neurosurgeon failed to find a tumour of the orbit through the transfrontal route. In the following case I came upon the neoplasm quite easily after temporarily removing the lateral wall of the orbit and retracting the external rectus muscle upwards. The neoplasm was dissected from the optic nerve and the eyeball. I do not think the access could have been more direct, and the exposure was certainly adequate. The note made on July 10, 1945, after left transfrontal craniotomy was: no neoplasm visible in the orbit.

Case Report

A woman aged 33 was referred to me by Dr M O Lavin on Dec 7 1945. She had left proptosis which she first noticed in August 1944. About June 1945, the temporal field of the left eye was lost. She was examined in July and all investigations were negative. Radiographs of the left optic foramen and canal showed no abnormality. At Oxford exploratory craniotomy was done through the left transfrontal approach. The prechiasmal part of the left optic nerve was normal. The roof of the orbit was removed and no neoplasm was seen in the orbit.

On examination on Dec 7 1945 she showed café au lait patches and soft raised swellings affecting the right arm, back, chest, anterior abdominal wall and left leg. The left eye was proptosed forwards and upwards, and on looking to the left ocular movements were limited—upwards downwards, and directly left. Her refraction had been 5.5D myopia and was 1D hypermetropia. The optic disk was oedematous prominent and appeared to be pushed forward into the eye. The physiological cup was filled by oedema. There were some highly refractile spots on the nasal side of the optic disk and some streaks extended from its temporal edge into the papillo-macular bundle. The macular area was deeply crimson and surrounded by pigmentary disturbance. Visual acuity was reduced to hand movements. Visual field loss was severe in the lower part of the field and on the temporal side. In the lower temporal quadrant the defect reached to 3° from the fixation point. She had been advised to have the left eye excised and the orbit partially exenterated.

A diagnosis of neurofibromatosis was made. The clinical findings suggested that the neoplasm in the left orbit lay inside the muscle cone and below the optic nerve possibly invading either its sheaths or the nerve itself. Radiographs of the optic foramen and canal showed no abnormality. The right eye and right visual field were normal. It seemed justifiable to explore the left orbit through its lateral wall and to remove the tumour by this route sparing the eye if possible.

On Feb 7 1946, lateral orbitotomy was done. A curved incision was made 5 mm behind the lateral margin of the orbit and coinciding with its curve. From the centre of this a horizontal incision was made posteriorly for 4 cm. These incisions were deepened to the periosteum of the malar bone and the temporal fascia. The flaps thus formed were undermined in the plane of the periosteum and temporal fascia upwards and downwards and reflected. An incision was made through the periosteum along the lateral orbital margin and this was carefully stripped from the orbital aspect of the lateral wall of the orbit. The space between the periosteum and the bone was temporarily packed with ribbon gauze. The temporal fascia was then incised along the posterior margin of the frontal process of the malar bone, and with a blunt dissector the temporal muscle was stripped from the bone. The space between the muscle and the bone was packed with gauze. The periosteum over the malar bone was incised in line with the inferior orbital margin and reflected for 4 to 5 mm. The same was done 5 mm above the external angular process. The gauze packs were now removed from the temporal fossa and from the space between the orbital periosteum and the bone and into the latter a metal guard was inserted. About 1 cm behind and in the same plane as the incision through the periosteum above the external angular process the point of an Archimedean drill was placed on the temporal side of the lateral wall of the orbit. The drill had a stop 5 mm from its tip. A hole was bored in the lateral orbital wall adequate in size to admit the looped end of Gigli's saw which was caught on the orbital side of the bone and drawn through and forwards. A saw cut was made forwards and it was completed in the line of the periosteal incision. A loop of Gigli's saw was then passed through the anterior end of the inferior orbital fissure and a cut made through the bone in a plane with the floor of the orbit emerging in the periosteal incision in the malar bone. The bone joining the drill hole with the inferior orbital fissure was then divided with a chisel cut the quadrilateral piece of the lateral orbital wall was held in bone forceps removed and placed in a bowl of warm sterile saline.

The orbital periosteum was then incised postero-anteriorly along the lower margin of the external rectus muscle from the level of the bony floor of the temporal fossa to within 5 mm

of the orbital rim. The external rectus belly and the periosteum were retracted upwards and with a blunt dissector the orbital fat was gently separated to expose the neoplasm which lay within the muscle cone below the optic nerve and mainly on its temporal side. The optic nerve was stretched over the neoplasm and displaced upwards and inwards. The neoplasm was greyish blue, had a smooth surface, was not attached to the globe and tapered posteriorly towards the apex of the orbit. It was defined by gentle blunt dissection mainly with the gloved forefinger. There was some difficulty in freeing its posterior extremity. Fig 1 (Special Plate) is a photograph of the neoplasm.

The lateral wall of the orbit was now replaced by a non touch technique holding the bone in forceps. The orbital periosteum and temporal muscle fell back into their normal positions. A split rubber drain was passed into the orbit at the junction of the lateral wall and the floor and another was laid over the temporal fascia parallel to the horizontal incision and emerging from its posterior extremity. The incision was repaired in two layers, the fat and subcutaneous tissues being sewn up with interrupted catgut sutures and the skin edges with interrupted sutures of number 00 black silk placed 2 mm from the edge of the incision and 3 mm apart. Vaseline gauze covered the wound and a pressure dressing was applied over this.

Pathological Report—The neoplasm measured 30 by 23 by 16 mm. After removal it was yellowish white in colour and had a smooth glistening surface and a rubbery consistence. Dr H F Brewer's histological report was as follows. The specimen was a circumscribed tumour of firm consistence and of oval shape 30 mm in its longest diameter by 23 mm by 16 mm. The approximate weight was 5.5 g (Fig 1). It was enclosed in a fibrous capsule which appeared to have ruptured at one point. The cut surface had a yellowish white translucent appearance. Section shows that the tumour consists of a loosely woven tissue in which spindle shaped cells the nuclei of which are narrow and slightly curved run in an irregular interlacing fashion. In the central part there is extensive collagenous change in the stroma, in another small area the tumour is very cellular but not of a degree to suggest a sarcomatous change. There is a scattered infiltration by small lymphocytes and the tumour is surrounded by a capsule. No nerve elements are recognizable but the histological and clinical features point to the tumour being a neurofibroma (Fig 2 Special Plate).

Post operative Course—The drainage tubes were removed 48 hours after operation. The wound healed by first intention and the lateral wall of the orbit united to adjacent bones in its normal position. The scar of the incision is scarcely visible. Papilloedema was subsiding on the fourth day after operation and had disappeared by the tenth day. Proptosis subsided but the left eye has remained higher than the right possibly the transfrontal craniotomy and the removal of the orbital roof may be factors in causing this. There remains slight limitation of action of the external rectus but all other ocular movements are normal. There is some dusky crimson discoloration around the left macula. Left vision has recovered to 6/6 with -5.25D sphere and the visual field has improved by 35° in the lower half where the main defect was present before operation.

Summary and Conclusion

A case is described of unilateral proptosis due to a neurofibroma 30 by 23 by 16 mm situated within the cone of the recti muscles and beneath the optic nerve. Transfrontal craniotomy had failed to reveal the neoplasm which was removed six months later after temporary removal of the lateral orbital wall. Vision recovered from hand movements to 6/6 and the visual field defect improved by 35°.

This case illustrates the value of exploration of the orbit in cases where a neoplasm is suspected as the cause of unilateral proptosis. It shows also that when the neoplasm is limited to the orbital contents and lies behind the eye the orbit may be effectively explored after temporary removal of the lateral orbital wall. I think this approach route is preferable to transfrontal craniotomy.

LIPOID PNEUMONIA: A PITFALL IN DIAGNOSIS

BY

R E REWELL MD, MRCP

Pathologist to the Zoological Society of London

(From the Department of Pathology, Guy's Hospital Medical School)

(WITH PHOTOGRAPHURE PLATE)

Changes in the lung produced by the introduction of oils appear to have been investigated first by Gueysson-Pellissier (1920), who injected olive oil into the trachea of the dog and the rabbit and found it to be removed from the alveoli by phagocytes without leaving any trace. The process was hastened if tubercle bacilli were ground up in the oil. Corper and Freed (1922) in an investigation of oils then commonly applied to the upper respiratory tract for therapeutic purposes, found that "proliferative broncho-pneumonia" followed the introduction of chaulmoogra oil, olive oil, or petrolatum into the lung of the rabbit. Laughlen (1925) reported three cases with the lesions now known to be typical of lipoid pneumonia—two infants receiving liquid paraffin as nasal drops and a man of 37 with 'multiple paralyses' taking it by mouth. He attempted to reproduce the condition experimentally, but killed his animals (rabbits) while the lesions were still in their early stages. Pinkerton (1927) reported similar cases, and in 1928 he published the results of experiments designed to discover an oil suitable as a base for the introduction of radio-opaque substances into the lungs. In the course of these experiments he made a thorough investigation of the ill-effects produced by some. He found that when vegetable oils were introduced they produced no tissue reaction and were expectorated in a few days leaving no trace. Animal oils, however, were first emulsified *in situ* and later attacked by phagocytes. Some of these reached the lymph nodes where fibrosis was set up after two or three months, but others remained in the lumina of the alveoli where the same process occurred. Foreign-body giant cells arose in both sites. Fatty acids produced by hydrolysis were the irritative agents, the total damage that resulted depending on the proportion of free fatty acids present in the original oil and on the rate of its hydrolysis. Chaulmoogra oil was unique in producing acute tissue necrosis from the start. Mineral oils were not hydrolysed; they produced an immediate phagocyte response in the alveolus and were rapidly emulsified. The droplets were transferred to the lymph nodes but here and in the alveoli fibrous tissue reaction followed far more slowly than with animal oils. In contradistinction to vegetable oils, however, the formation of fibrous tissue was inevitable eventually.

Since these studies several series of cases have been described (Ikeda, 1937, Paterson, 1938, Graef, 1939, Young Applebaum, and Wasserman, 1939, and Pinkerton and Moragues 1940). All these except one occurred in infants or in debilitated, aged, or paralysed people who were taking animal or mineral oil by mouth or as nasal drops. The exception was an apparently healthy young woman who was taking cod-liver oil by mouth (Young Applebaum and Wasserman 1939). It is noticeable that only the series of Paterson seems to have been reported in this country, which is surprising in view of the fact that he found as many as eight cases in 813 consecutive necropsies at a general hospital.

The gross lesions reported in the lungs vary from a generalized consolidation by greasy material resembling red hepatization to local areas of fibrosis surrounding a mass

of necrotic tissue and oil which ranges in size from a milium to a 'paraffinoma' several centimetres across. Several observers record fibrotic nodules resembling milia in other organs—for example, in liver, lung, and spleen by Pinkerton and Moragues, and in kidneys, adrenals, and ovaries by Young, Applebaum, and Wasserman. These last observers found the fibrosis to be so extensive as to produce arteritis and periarteritis in the kidney, with considerable glomerular damage. In nearly all these cases the diagnosis was unsuspected during life. Where trouble in the chest was suspected (Graef, 1939), radiographs showed shadows near the hilus of the posterior dependent parts, and these did not alter in appearance over some months. Most of the cases were discovered at necropsy, and the cause of death had generally been considered on clinical grounds to be due to other causes. In many the lipoid pneumonia may well have been of only minor importance.

The following case, showing many of the typical features described above, occurred in a healthy young woman from whom no history of the ingestion or aspiration of an oil was ever obtained, and it emphasizes the difficulties in the diagnosis of such a case.

Case Report

The patient was a healthy and intelligent member of the Women's Land Army, aged 19 at the time of death. She was admitted to hospital on July 4, 1945, with an acute febrile illness resembling rheumatic fever with erythema nodosum. Nothing abnormal was found on clinical examination of the chest, cardiovascular system, or the abdomen. The temperature was 100.2° F (37.9° C), the pulse 120 and the respirations 22. The fauces were injected, and there were raised red patches on the legs. She did not complain of cough.

A radiograph of the chest (Fig 1, Special Plate) showed a collapsed right middle lobe and enlarged mediastinal lymph nodes. The patient recovered quickly from her acute episode, and the patches on the legs cleared up. The blood picture was normal, the radiographic appearances were unlike tubercle, and the sputum was repeatedly 'negative,' and so, by exclusion, a diagnosis of Hodgkin's disease was made, a reticulo endotheliosis being the only plausible explanation that could be found for enlarged mediastinal lymph nodes in a young woman without changes in the lung fields. Two courses of deep therapy were given without producing any marked change in the mediastinal shadows.

The patient was readmitted on April 30, 1946. She was dyspnoeic with enlarged neck veins and shallow respirations. The percussion note over both upper zones of the chest was impaired and bronchial breathing was heard there. Radiographs showed an increased mediastinal shadow and infiltrations near the lung roots (Fig 2, Special Plate). She died on May 12.

Findings at Necropsy—Recent fibrinous exudate extended all over the pericardial surfaces and a little excess of fluid was present in loculi among this. The air-passages were all acutely inflamed. A small quantity of clear fluid was free in each pleural sac, but the serous surfaces were normal. All the mediastinal lymph nodes were enlarged, forming a dense mass which surrounded the main bronchi and compressed them to a moderate degree. The nodes were discrete, but bound together by much fibrous tissue. Their substance was firm quite uniform in consistency and appearance, and of a definite pinkish tinge. No normal lymphoid tissue appeared to remain at all. The lungs were firm and solid especially in the upper lobes. No discrete nodules appeared on their surfaces. On gross section the upper lobes were seen to be infiltrated extensively by firm pinkish material which was most abundant near the hilum and appeared to spread out in tentacles through the upper lobes. Its cut surface was quite dry, was certainly not greasy, and showed no sign of breaking down or of surrounding inflammation. Many circumscribed patches of the same appearance lay in the lower lobes. The intervening lung substance revealed oedema but no obvious bronchopneumonia; there were no areas of collapse and no abscesses. The spleen showed prominent follicles but no obvious infiltration. The liver showed only chronic

passive congestion. The uterus was menstruating. No other abnormalities were found in any system.

Histological Appearances—Sections of the lungs prepared from material embedded in paraffin revealed an intense histiocytic activity throughout the alveoli. Many macrophages lay free in the lumina, the cytoplasm of the majority being distended and of a foamy appearance. The endothelium of the alveoli had been shed and fibrous tissue surrounded the macrophages in the lumina, but the extent to which this had taken place varied much throughout the sections. Fig 3 (Special Plate) shows a typical area. In frozen section the macrophages were seen to be distended with fat globules which stained with scarlet red (Fig 4, Special Plate). Unfortunately the true nature of the condition was not understood at necropsy, so that sufficient material to identify the fat by differential staining was not saved. In the mediastinal lymph nodes the fat globules were again obvious in frozen sections. Intense histiocytic activity and formation of fibrous tissue were evident and giant cells of the 'foreign body' type were numerous (Fig 5, Special Plate). Very similar areas were seen in the spleen and liver. These were small, and superficially they resembled tuberculous milia, but on close examination they were seen to contain phagocytes instead of epithelioid cells and the giant cells were once more of the foreign body type (Figs 6 and 7, Special Plate).

Discussion

Origin of the Oil—Careful inquiries were made of the patient's family, friends, employers, and medical attendants to discover whether or not she had come into contact with any oil either as nasal drops, or by mouth, or as a spray in connexion with her work, but no evidence whatsoever was obtained that she had used any such substance.

The Differential Diagnosis—The diagnosis of lipoid pneumonia would be difficult in the absence of an obvious history of ingestion or inhalation of an oil or fat, especially in a healthy adult. In the above case the early enlargement of the mediastinal lymph nodes in the absence of lung shadows was highly suggestive of Hodgkin's disease, especially with a normal blood picture. As the response to treatment with radiation was so poor, this diagnosis might have been reconsidered, but few alternatives presented themselves, and none with a better prognosis.

The Genesis of the Lesions—In the above case the great outpouring of phagocytes into the alveoli would seem to indicate that the condition was due to a mineral oil, as found by Pinkerton (1928) and quoted above. The fibrous tissue present in the lung was more abundant than in Pinkerton's cases of this type, but it may well have been due to the deep therapy. However, such fibrosis did develop in his cases eventually. Although developed in response to a chemical irritant, this fibrous tissue has none of the specific character as is seen, for example, in silicosis. The degree of fibrosis developed in other tissues would not seem to depend so much on the nature of the irritant. It is noteworthy that similar lesions may arise in lymph nodes where excess of fat is present from causes other than inhalation. Thus Hill (1937) and Glynn and Rosenheim (1938) found fibrosis and foreign-body giant cells round masses of fat accumulated in the abdominal lymph nodes in steatorrhoea, while Vaux (1943) found foamy macrophages in what may have been earlier lesions of the same nature. It is evident, then, that such irritation may accompany the presence of fat in lymph nodes and may be responsible for the lymphatic obstruction in the sprue syndrome. It may be part of a vicious circle in which more and more fibrosis would lead to the progressive accumulation of fat.

Summary

A case of lipoid pneumonia in a young woman is described. The origin of the inhaled oil is uncertain. The condition is more common than is often supposed and should be considered

as a diagnosis in any case where chronic infiltration of the lung fails to respond to treatment

The pathology is that of a chronic response to irritation and is produced by animal or mineral oils. In the former case hydrolysis of the oil to fatty acids leads to more rapid development of fibrosis than in the latter. Similar appearances may be seen in the lymph nodes of this condition and of sprue and it is suggested that they may be of similar origin

I have to thank Dr W Lindsay Locke for the radiographs Mr J F Carter Brune, Dr Locke, and Dr P R C Evans for permission to publish the clinical notes, and Messrs Ilfords for the photographs

TERATOMA OF TESTIS

SPONTANEOUS DISAPPEARANCE OF LUNG METASTASES

By

J EWART SCHOFIELD, FRCS

Swindon Wilts

[WITH PHOTOGRAPHIC PLATE]

The following report of a case which showed evidence of the spontaneous disappearance of lung metastases will be of interest.

Case Report

In September, 1941 a youth aged 16 was referred to me by Dr A Gibson with a swelling of the right testicle. It was the size of a Jaffa orange heavy, painless, but slightly tender. The cord was thickened. There was an indefinite swelling in the upper abdomen. The Wassermann reaction was negative. The radiologist's report on an x-ray examination of the chest read as follows: Multiple, circular sharply defined opacities in both lungs. They are of varying sizes, and are largest and most numerous in the lower zones. Intermediate sizes are seen in the mid zones. There is no surrounding lung reaction around these opacities, the appearance of which is typical of secondary malignant deposits. There is no evidence of tuberculosis. The mediastinal glands are not enlarged. (Plate Fig 1) A diagnosis of malignant testicular tumour with abdominal and lung metastases was made and, in view of the metastases the boy's parents were told that operation was not advised and that the expectation of life was only a few months.

In July, 1945 almost four years later, he was referred to me again by Dr Gibson who wished to know why the patient was still alive. Indeed I was extremely surprised to see him myself and so far as I could remember, his general appearance had improved. Dr Gibson stated that during the last four years the testicular tumour had varied considerably in size from that of a duck's egg to a Jaffa orange. The tumour of the right testis felt softer was slightly fluctuant and was a little larger than in 1941. An indefinite abdominal mass could still be felt. The x-ray appearance of the lungs was rather startling. The radiologist reported: The only abnormality seen is a small round opacity in the left lower zone. In view of the previous x-ray appearance this shadow should be presumed to be a metastasis. The complete disappearance of all the other metastases is remarkable.

It was now considered justifiable to advise surgical treatment and a right orchidectomy was performed, the cord being divided at the internal abdominal ring. Under the anaesthetic

a definite mass of abdominal glands was palpated. Macroscopically the testicle had the appearance of a breaking down tumour, yellowish in colour, with many cysts and cartilaginous nodules. The report of the pathologist on a microscopical section of the tumour read: The tumour appears to be a teratoma of the testicle, surrounded by a fairly dense fibrous capsule. The structure includes various tissues, the most prominent being cyst like spaces of various sizes lined with columnar or flattened epithelium. Nodules of cartilage are also present, embedded in the stroma, which is composed of loose fibrous tissue containing fibres of smooth and striped muscle. There are some masses of undifferentiated cells suggestive of a malignant element which is common in this type of tumour. It is considered, moreover, that all such testicular teratomata are potentially malignant and should be treated accordingly.

The operation and convalescence passed off without incident after which the patient's general condition improved, with increase of appetite and weight. The last report of the radiologist on a recent skiagram of the chest states that there is no evidence of abnormality. (Plate Fig 2) Despite frequent examination of the abdomen it is difficult to say whether the abdominal mass has completely disappeared.

The unorthodox course of the disease led me to inquire carefully into the patient's habits occupation diet etc after I first saw him in 1941 and pronounced the case inoperable. It appears that he was employed in a bakery until February 1942 after which he obtained work in an aeroplane factory for twelve months. Here he breathed an atmosphere containing duralumin dust. From January, 1943 until July 1945 he did casual work on a farm. He had no peculiar habits or liking for any particular article of diet.

Discussion

It is not intended here to expound on the subject of teratoma of the testis, for the literature on the subject is voluminous. The salient feature of the case described is that the lung metastases disappeared spontaneously. One hears from time to time of the spontaneous disappearance of malignant tumours, but the disappearance of secondary deposits in the lungs must be a rare occurrence. Saleeby (1944) quotes two cases of teratoma of the testis with metastases which recovered, but only after treatment. The treatment consisted of removal of both testicles for Saleeby wondered if there was a relation between sex hormones and cancer and thought that some carcinogenic agent is influenced by removal of both testes. One case his own was a patient who had a teratoma of the left testis with a large metastatic retroperitoneal mass. He was treated by bilateral orchidectomy, supplemented by deep x-ray therapy. The patient was well after fourteen months, and the retroperitoneal mass had disappeared. The other case quoted by Saleeby was Dr McClelland's in which lumbar and lung metastases disappeared within twelve months of bilateral orchidectomy. This treatment was followed up by Harrison (1944), who treated three more cases of teratoma of the testis by bilateral orchidectomy and deep x-ray therapy. Reporting these cases he stated that two of these patients died and the third was rapidly approaching dissolution. Harrison sums up by saying that "there is no clinical evidence to show that the course of the disease was affected by the operation."

In my own case it will be noted that the lung metastases disappeared before the primary growth was removed, and that deep x-ray therapy was not given—in fact, there was no treatment of any description. It was only after observing the disappearance of lung metastases that it was decided to remove the tumour of the testicle.

In discussing this subject one cannot fail to draw a comparison with chorio-epithelioma. In this disease a number of cases are known in which lung metastases have disappeared, but only after removal of the primary growth by hysterectomy. Teacher (1935) mentions cases in which

chorio epithelioma with pelvic extensions has spontaneously disappeared, but does not quote a case of disappearance of lung metastases except after hysterectomy. Comparison with chorio-epithelioma is interesting, as teratoma of the testis can contain chorio-epithelioma, although none was seen in the slide of my case.

I should like to thank Dr Paul Cave for his reading of the x ray films and Col F R Coppinger for his opinion on the pathology of the tumour.

BASAL-CELL CARCINOMA AT SITE OF TRAUMA

BY

T G REAH, MD, MRCP

Late Lieut-Col R A M C

[WITH PHOTOGRAVURE PLATE]

Schrek (1941) in a review of 296 cases found that in five instances patients suffering from a basal cell carcinoma gave a history of the growth developing on the basis of an old scar. In one case the carcinoma appeared about 15 years after a burn of the forehead, in another it occurred two years after a burn of the hand, while in a third the growth developed 30 years after an avulsion of the scalp. No interval is stated in the remaining two cases, in one of which the growth appeared in a scar on the nose and in the other in scars of the legs following Roentgen-ray burns. Aitken (1944) stated that it is unusual to obtain any history of injury in cases of rodent ulcer, and cited one case where the history was certainly suggestive.

In the following case the history suggests the development of a basal-cell carcinoma immediately after a superficial cannon-shell wound. It should be remembered, however, that in the Middle East the incidence of secondary infection was high and delayed healing of superficial wounds common, and it is therefore impossible to determine the time of onset of malignancy.

Case Report

A regular soldier aged 31 with 13 years service was admitted to a military hospital in West Africa on Feb 11 1946 suffering from a short-term fever. He had served in the Middle East from 1935 to 1944 and in November 1942, was struck on the

Photograph showing lesions on right temple

right temple by fragments of a cannon-shell from an enemy aeroplane. The injury was superficial consisting of an abrasion about 1 cm in diameter and after the application of a dressing

he returned to duty. This abrasion did not heal. In August 1943 he noticed a sharp edge projecting just above the site of the abrasion, and a spicule of metal about 0.5 cm long was removed by the regimental medical officer. The puncture hole also did not heal thereafter both this lesion and the original abrasion slowly increased in size and bled freely if the surfaces were rubbed.

Midway between the outer canthus and the right ear was an ovoid slightly depressed area 3.5 by 1.7 cm with a finely nodular base covered by pale epithelium except for the posterior 0.75 cm where the surface was slightly scaly. Immediately above this lesion was another 1.7 by 1 cm with an irregular outline covered by a crust and with no characteristic edge (see photograph). There was no clinical evidence of metastases. There were three pigmented naevi up to 0.5 cm in diameter on the face, numerous pigmented naevi up to 0.3 cm in diameter on the trunk and limbs and four pedunculated pigmented warts on the trunk, all of which the patient stated had been present for years. A piece of the upper lesion was removed by Lieut Col D H Mackay and Major A F Mohun reported that it was a typical basal cell carcinoma (Special Plate Figs 1 and 2). I am grateful to them for their assistance.

My thanks are due to Major G M Ardran for the photograph of the patient, to L/Cpl D Winks for the photomicrographs, and to the D G, A M S and Col W R D Hamilton for permission to publish this case.

FOLIC ACID IN PERNICIOUS ANAEMIA ITS EFFECT AS SHOWN BY SERIAL STERNAL PUNCTURES

BY

HERBERT LEVY, MD, MRCP

Assistant Medical Officer Bethnal Green (LCC) Hospital

In bone-marrow films of three cases of pernicious anaemia Davidson *et al* (1942) observed a considerable decrease in the proportion of early megaloblasts only six to ten hours after a single intramuscular injection of anahaemin or reticulogen. It seemed of interest to investigate the rate of bone-marrow changes following a single oral dose of 50 mg of folic acid.

In order to present figures comparable with those of Davidson *et al* the classification of nucleated red blood cells adopted by these authors (cf explanation to Table I) was used, but cells in mitosis were not differentiated into the various groups. This classification admittedly makes no attempt to differentiate between cells derived from megaloblasts and those developing along normal lines. As stated by those authors, "a certain arbitrary judgment is sometimes necessary for the classification of a given cell which falls on the borderline between groups." A further difficulty is the fact that changes in cell size, in haemoglobinization of cytoplasm, and in nuclear structure proceed during the repair stage of pernicious anaemia at different rates. For instance, after treatment a not inconsiderable proportion of deeply basophilic cells of under 11 μ diameter are found which have a nucleus similar to cells of Type II before treatment; this cell type is characteristic for all conditions in which there is abnormally intense erythropoiesis.

Pernicious anaemia in a man aged 63 was first diagnosed on his admission to Bethnal Green Hospital in December 1936; this responded promptly to liver treatment. He was followed up and treated as an out-patient until November 1937 but failed to attend after that date and has not since had any treatment with liver or stomach extracts. He was readmitted on Aug 23 1946 with pernicious anaemia in relapse and with gross

symptoms and signs of subacute combined degeneration of the cord Haemoglobin 947 g per 100 ml, red cells, 2 130,000, MCV, 128 μ , reticulocytes 3%, white cells 6,300 (neutrophil polymorphs 2,331, eosinophil polymorphs 378, basophil polymorphs, 63 lymphocytes 3 402 monocytes, 126)

TABLE I—Sternal Marrow Counts representing Percentage of 500 Nucleated Red Blood Cells in Each Film

	Type				Mitoses
	I	II	III	IV	
Before folic acid	46.0	22.8	12.4	17.0	1.8
6 hours after	22.8	27.2	31.2	14.6	2.2
12	10.0	18.4	43.4	20.4	2.8
24	7.0	17.4	56.6	16.8	2.2
48	8.4	19.0	45.0	26.2	1.4
Davidson <i>et al</i>					
Case 1 { Before anahaemin	42.0	28.3	24.0	5.7	9.0
6 hours after	25.7	38.5	25.5	10.3	12.4
Case 2 { Before anahaemin	46.2	30.4	9.8	13.6	10.2
10 hours after	35.8	44.2	13.8	6.2	18.4
32	8.4	53.6	30.8	7.2	24.3
Case 3 { Before anahaemin	40.2	38.4	15.0	6.4	14.4
8 hours after	19.8	51.7	19.7	8.8	11.5

Type I Cell of average 18 μ diameter pale nucleus with fine lattice of chromatin sometimes with nucleoli Type II Average 14.2 μ diameter nucleus more deeply staining and coarser chromatin pattern Type III Average 11 μ diameter cytoplasm basophilic polychromatic or orthochromatic deeply staining nucleus with lumpy masses of chromatin Type IV Average 9 μ diameter polychromatic or orthochromatic with pyknotic nucleus Mitotic erythroblasts Characterized by deeply staining chromosomes (cf LaCour 1944) For the cases of Davidson *et al* mitotic cells are listed separately but are also included in the figures under Types I-IV

It is thus seen that folic acid by mouth effected as rapid and extensive a decrease in Type I cells as did intramuscular refined liver extract The increase in Type III erythroblasts following folic acid as compared with Type II in the series of Davidson *et al* may be due to a difference in assessment rather than in quality of response

The rapidity of the change in the bone marrow from a megaloblastic to a normoblastic picture was thought by Davidson *et al* to support the view 'that normoblasts can be derived directly from megaloblasts' and 'that megaloblasts and normoblasts belong to one developmental series Table II shows, however, that the proportion of nucleated red blood cells with deeply basophilic—that is, non-haemoglobinized—cytoplasm is considerably larger six hours after treatment than it was before treatment, the basophilic cells belonging to Types I to III I have in the past observed the same phenomenon in all cases of pernicious anaemia in which I have examined sternal-marrow films before and shortly after liver treatment

TABLE II

	Basophilic	Polychromatic	Orthochromatic
Before folic acid	24.8	59.4	15.8
6 hours after	57.6	32.2	10.2
12	43.4	40.6	16.0
24	57.4	34.0	8.6
48	45.8	43.0	11.2

Percentages represent 500 nucleated red cells

The objection that the figures in Table II do not necessarily indicate an absolute increase in the number of basophilic erythroblasts seems refuted by Table III, which shows a probably significant rise, and in any case not a fall in the erythroblast population

TABLE III—Myelo erythroblastic Ratio

	Cells of Myeloid and Lymphoid Series	Nucleated Red Blood Corpuscles
Before folic acid	363	137
6 hours after	340	160
12	350	150
24	337	163
48	294	206

As it seems scarcely possible that a partly or fully haemoglobinized megaloblast should lose all its haemo-

globin during its further development this finding shows that repair in pernicious anaemia is effected by newly produced cells of a non-megaloblastic series Naegeli (1931) described as late megaloblasts fully or nearly fully haemoglobinized large oval-shaped rather than spherical cells, with an eccentric rather than central, deeply staining more or less pyknotic nucleus, Israels (1939) and Wilson (1942) reached the same conclusion The number of these cells in the films after treatment is quite consistent with the view that they are the cells derived from the early, partly or not yet haemoglobinized megaloblasts of the untreated marrow and that they play quantitatively no material part in the repair of pernicious anaemia

The disturbance of granulopoiesis characterized by the presence in large numbers of giant metamyelocytes and giant band-shaped granulocytes—due according to LaCour (1944), to nucleic acid shortage of the promyelocytes producing incomplete spiralization of the r chromosomes—showed no appreciable change in the four marrow films made after the administration of folic acid This is in agreement with previous personal observations on marrow films examined one to two days after the beginning of liver treatment, and with the findings of Zuelzer and Ogden (1946) in cases of megaloblastic anaemia in infancy treated with folic acid in which they observed its disappearance only after two to four weeks, whereas in at least one of their cases the megaloblastic pattern had disappeared two days after parenteral folic acid treatment

I wish to thank Dr H A Ash for the peripheral blood examinations and Dr I Doniach for his criticism

Medical Memoranda

A Rare Form of Tuberculous Meningitis

Four cases of an unusual variety of tuberculous meningitis occurred in adults in Singapore during the period 1938-42. Each case presented the following features: a period of pyrexia; a period in which spinal symptoms predominated, and a period of meningism passing on to coma and death. Each period lasted about a week.

CLINICAL FEATURES

Pyrexial Period—There were no pronounced distinguishing features during this time. Three cases were admitted for routine investigation for fever of unknown origin and the fourth Col Rogers' case for fever associated with diarrhoea. The pyrexia was of a regular remittent type, not rising much above 102° F (38.9° C). It was associated with a mild leucocytosis up to 12 000 (80% polymorphs).

Spinal Symptoms—These were the first symptoms of major importance which distinguished the illness from the run of tropical fevers undergoing routine investigation. The first manifestation in all cases was difficulty in passing urine leading to retention. This was followed within 24 hours by a paresis of the lower extremities which gradually deepened but never became complete. There was diminution of muscle tone, loss of superficial and deep reflexes and an absent or equivocal Babinski sign. These findings were associated with a rising sensory level which was peculiar in that it was patchy and extremely difficult to determine precisely. Sensory loss was most marked to pin-prick, hot and cold, postural sensibility, vibration sense.

and touch were little affected. The calves were not unduly tender. There were no root prisms. From a consideration of the Chinese cases alone this might have been beriberi occurring during the course of tuberculous meningitis, in which disease early bladder symptoms are common, particularly as pyramidal release was never demonstrated. The fact, however, that a case occurred in a Sikh and a British soldier practically rules out this possibility. Lumbar punctures performed at various periods during the second week showed spinal block, a yellowish fluid more green than is usual in Froin's syndrome, and an excess of cells, mainly lymphocytes, up to 500. The protein rose as high as 900 mg per 100 ml. The tubercle bacillus was never found. In three cases radiology of the spine revealed no pathological change.

Period of Meningism.—This period lasted up to 10 days. It was associated with headache and as this disappeared the patient became confused. Brudzinkis neck sign was usually not markedly present until well on in the second week—that is, after the spinal symptoms had been in evidence for some days.

PATHOLOGY

A full necropsy was performed on two cases, in two the brain and spinal cord alone were available. Both cases in which necropsy was made revealed subclinical fibroid phthisis without cavitation. The appearance of the spinal cord was characteristic. It looked as if a yellow jelly had been poured into the subarachnoid space and had been allowed to set but that this had been incomplete in the lower cervical areas. A few tubercles could be found in the meninges of the cord. The brain showed typical small tubercles in the arachnoid, in which acid fast bacilli were demonstrated. The fluid in the basal cistern was relatively clear. It contained considerably less protein and fewer cells. Section of the cord showed very little save peripheral commencing degeneration of myelin round the full circumference of the cord (osmic acid) to the depth of about 2 mm.

COMMENT

This syndrome is recorded mainly because, though known to occur its features are not referred to in standard works. On this account the first case caused considerable difficulty in fact it was not diagnosed correctly until the necropsy. Since that time we have not seen an exactly similar case, though Dr Purdon Martin recently had one at Queen Square, in which the cerebrospinal fluid findings early on tallied with the above. Dr Greenfield, in discussing this case, remarked that in his experience when the cerebrospinal fluid protein was very high he has been unable to demonstrate tubercle bacilli. In view of the necropsy findings cisternal fluid might be more productive. It is worthy of comment that Lieut.-Col. J. M. Rogan, to whom our thanks are due, correctly diagnosed the British case during the period of the spinal phase from his knowledge of the Asiatic cases.

G. A. RANSOME
E. S. MONTIERO

Nicotinamide and Diabetes Mellitus

The water-soluble vitamins have been shown to play a part in enzyme systems involved in the oxidation and fermentation of glucose, and the beneficial action of yeast in the treatment of diabetes mellitus has been recognized for over 50 years. Dienst in 1939 reported the results of experiments on six human diabetics: his patients were given diets of known carbohydrate, protein, and fat content, and after stabilization and control over a period of several weeks the diets were supplemented with vitamin B (whole group) and ascorbic acid. He reported that the sugar tolerance in all cases was much improved thereby and concluded that this was due to the action of thiamine and ascorbic acid. In 1937 Martin had shown that the existence of a multiple vitamin deficiency increased the insulin requirements of depancreatized dogs, but did not form any definite conclusion as to the precise role of the vitamins in treatment. Gaebler and Ciszewski (1945) fed three depancreatized dogs on a standard diet with added pancreatic enzymes and yeast. The minimal dose of insulin necessary to control glycosuria was inadequate when yeast was removed from the diet, and glycosuria was abolished after 12 days when the

ingestion of yeast was resumed. The effects of yeast be produced with thiamine, riboflavin, nicotinic acid, inositol, pyridoxine, pantothenic acid and para-aminobenzoic acid. In one animal no relation between the insulin requirements and the water-soluble vitamin intake could be demonstrated and in the other two dogs thiamine, riboflavin, and nicotinic acid given together only delayed the onset of glycosuria. From this it may be concluded that although yeast prevents glycosuria in depancreatized dogs under the conditions of this experiment it is not possible to state which component of yeast is solely responsible. They were unable to confirm Dienst's view that an excess of ascorbic acid was beneficial in reducing the insulin requirements.

PRESENT INVESTIGATION

There is then some clinical and experimental evidence that yeast and the water-soluble vitamins can reduce the insulin requirements in human diabetes but there still exists considerable doubt not only as to the active principle concerned but also as to its mode of action. The case described by Gordon in a recent letter of a male diabetic aged 40 not on insulin, who seemed to have his tolerance for sugar increased by large doses of nicotinamide (1,200 mg daily for one month) is therefore of considerable interest in this connexion. We decided to investigate further the effect of nicotinamide on diabetics under control conditions in hospital. Accordingly six adult diabetics who were adequately stabilized without insulin on a fixed diet of 1,800 calories were chosen. They fell in the age group 40-65. Sugar tolerance estimation was performed after a few days' observation, and nicotinamide in a dose of 600 mg t.i.d. was given by mouth for 14 days. Sugar tolerance estimation was repeated at the end of this period and meanwhile daily blood sugar estimations had been performed. Surprisingly few side reactions were observed from this large dose of nicotinamide, the most constant being a general feeling of warmth and occasional severe flushing and tingling of the skin, face, and extremities. In no case did the sugar tolerance curve improve on this therapy, and the daily blood sugar levels were consistently steady throughout. As an example one case will be described in more detail.

CASE REPORT

This was a married woman aged 52, with no family history of diabetes, who had been a known diabetic for 12 months. She was admitted to the Manchester Royal Infirmary, under the care of Prof. T. H. Oliver, from the diabetic clinic. The sugar tolerance on July 4, 1946, was as follows:

Fasting blood sugar	216 mg per 100 ml
Blood sugar 1/2 hour after 50 g glucose	340
1	320
1 1/2 hours	340
2	310
2 1/2	255

Sugar was present in the urine throughout. She received 1,800 mg nicotinamide daily for 14 days with only slight flushing of the face and occasional tingling of the hands and feet. A sugar tolerance test was repeated on July 18, with the following result:

Fasting blood sugar	226 mg per 100 ml
Blood sugar 1/2 hour after 50 g glucose	300
1	335
1 1/2 hours	365
2	350
2 1/2	315

She has been seen on subsequent occasions in the out-patient clinic and there has been no change in her diabetic condition.

COMMENT

Although it is realized that the findings in six cases are inadequate for definite conclusions, there is no evidence that nicotinamide alone does influence the sugar tolerance or improve the diabetic condition.

I am indebted to Prof. T. H. Oliver for his help and co-operation.

BIBLIOGRAPHIC INDEX OF LEPROSY

Índice Bibliográfico de Lepra 1500-1943 Volume I A-H
By Luiza Keffer (Pp 674 No price given). Brazil São Paulo,
Rua Conde de Sarzedas, 38

Luiza Keffer and the other members of the staff of the library of the Leprosy Prevention Department of the State of São Paulo, Brazil, have rendered a great service to leprologists all over the world by their ten years' labours in preparing this monumental *Bibliographic Index of Leprosy*, the first volume of which has now appeared. All the works and papers included in their library, but it is much more than a catalogue of papers, for the contents of each have been entered on card indexes, and all the more important points which amount to even in a sample mentioned in an explanatory preface in French and English, are separately entered. For example under 'Diagnosico' twenty-five double column pages, with a number of subheadings, repeat the full references to papers which also appear under the authors' names. This multiplication of entries of each paper adds much to the convenience of reference, although it also greatly increases the bulk and accounts for the first volume of 674 pages covering the ground only from A to H. The completeness of the entries of all publications or several decades back is shown by eleven columns being devoted to the publications of the Brazilian authority H. C. S. Araújo and five to the writings of R. G. Cochrane. Again, fifty-two columns are devoted to the heading of chaulmoogra.

The entries are not limited to purely medical publications, but include those dealing with juridical, social, and literary points of view. Yet the author modestly writes of this 'unpretentious work'. On testing its completeness we have found only a few omissions of works of seventy or more years ago, such as those of L. Hillis Brouse, and Hildebrand, which have doubtless long been out of print and so are not available to the great Brazilian library. This work should find a place in every medical library, including those of leprologists engaged in investigations on a subject which is attracting the ever-increasing attention of the medical profession and of sociologists.

LEONARD ROGERS

MIND AND NERVE

Éléments de Psycho-Physiologie By Henri Roger (Pp 428 350 francs) Paris: Masson et Cie 1946

This is an important account of the relation between the study of the physiology of the nervous system and of psychology. The author believes with Claude Bernard that psychology should be regarded as a chapter in the book of physiology, though he allows that this chapter is of such significance that it may overshadow the rest of the book. His philosophical outlook is deterministic though not bigoted. Man's behaviour is determined by a conflict between the impulses of his innate instincts and the code of action imposed upon him by his environment (cf. the Freudian id and superego). Sometimes one is in the ascendancy and sometimes the other, but Dr Roger scarcely admits that the individual himself has any share in determining the result.

The book begins with a historical survey, followed by a description of methods of study of psychophysiology. The essential data are instincts and intelligence; the author does not think that there is any essential difference between the two. If the subject is studied from the evolutionary and phylogenetic viewpoint it is possible to trace the development of instinctive response to environmental stimuli progressing *pari passu* with brain development up to the diencephalon, and then with the appearance of the cortex, the emergence of intellectual response to similar or analogous stimuli. For example, Roger claims that it is possible to trace progress from the instinct to eat to the art of cooking and the science of dietetics, from the herd instinct to the social services and the organization of human family life, and so on. He recounts such knowledge as we possess of the cerebral function which underlies intelligent behaviour, as well as emotional mani-

festations and the formation of the sentiments. In the last part the more difficult psychological problems such as free will, sleep, dreams, and conscious and unconscious behaviour are dealt with along the same lines. While many psychologists think that any attempt to correlate their studies with physiological processes is an undue curb on their ideas and many physiologists consider that psychological correlations are often unscientific and nothing but 'viewy' theories, the psychiatrist and the medical practitioner must glean what they can from both camps. Roger's attempt to yoke psychology to physiology repays study.

MATERIA MEDICA

Materia Medica for Nurses By Lois Oakes, S.R.N., D.N., and Arnold Bennett M.P.S. Second edition (Pp 354 7s 6d, plus 6d postage) Edinburgh: E and S Livingstone 1947
Repertorium Pharmazeutischer Spezialpräparate Sera und Impfstoffe By Dr Herbert Ludwig (Pp 1308 48 Swiss francs) Basle: Verlagsgesellschaft Beobachter A.G.

The first is a textbook of suitable size for nurses and can be recommended. It is well printed and easy to read, and the diligent student who masters its teaching will one day be a ward sister of great competence. The brief description of the uses of different drugs is not always accurate (for example strophanthus is said to have an antipyretic action), and the authors would be well advised, when preparing the next edition, to check their statements by reference to a standard work such as *Pharmacology* by J. H. Gaddum.

The other is a book of reference, prepared in Switzerland, of all kinds of pharmaceutical specialties made by firms in every country. It should be of value to those who are asked by a patient for some new foreign medicine. He has heard of the different preparations are given in alphabetical order—the name of the firm, the components, though not the amounts, the indications for prescribing the preparation (too briefly), the size of packings and the price, the dose, the date when the preparation was introduced. It is written in German and is a tome of 1,300 pages, so the list of preparations should be fairly complete.

J. H. BURN

ELECTROCARDIOGRAPHY

Electrocardiography Including an Atlas of Electrocardiograms By Louis N. Katz, M.D. F.A.C.P. Second edition thoroughly revised (Pp 883, 525 engravings, including over 1,000 electrocardiograms 60s) London: Henry Kimpton 1946

Exercises in Electrocardiographic Interpretation By Louis N. Katz, M.D. F.A.C.P. Second edition, thoroughly revised (Pp 288, 141 engravings, containing 166 electrocardiograms 30s) London: Henry Kimpton 1946

New editions of these two companion volumes, by Dr Louis N. Katz, have appeared four years after the first publication of this work. Extensive revision, a considerable increase in size and the addition of more than a hundred illustrations to *Electrocardiography* indicate the growth of this subject.

In electrocardiography to-day attention is being focused on the chest leads. The author now employs CF, CF₁, and CF₂ as a routine. In these leads the left leg is paired with electrodes placed in turn just to the left of the sternum, in the mid-clavicular line, and in the anterior axillary line. He rightly insists that the addition of one chest lead, say CF₁, to the limb leads is not an adequate procedure. However, omission of any one of the six chest leads may result in failure to demonstrate an infarction of the heart, though in practice it is hardly feasible to take all six leads in every case of heart pain or suspected myocardial disease. The problem therefore becomes one of deciding which chest leads are most appropriate as a routine and in particular cases. In Britain chest leads are more usually paired with the right arm, and most workers here would agree that CR₁ or CR₂, with CR₃ and CR₄, are those most likely to give useful information. With regard to variations of the normal, Dr Katz shares the experience of others in finding that previous standards of normality were rather too rigid; this adjustment of outlook is the result of combined cardiographic and radioscopic observations of large numbers of normal recruits for military service.

The volume of exercises in interpretation has undergone modification and substitution of records in conformity with the

revision of the main work which remains one of the standard books on the subject and one to which great care and exhaustive study have manifestly been given at every stage in its production

SPECIAL SURGERY

Spezielle Chirurgische Therapie für Studierende und Ärzte By Dr Max Spegessci (Pp 884 illustrated 80 francs) Berne Medizinischer Verlag Hans-Huber

The best part of this book is the illustrations, the worst is the binding, the copy sent to us being already partly disintegrated despite careful handling. This may be the result of present conditions but it is regrettable for the quality of print and paper, like the illustrations, is good. The whole field of general surgery is covered—eye, ear nose and throat and gynaecological operations being excluded. There are special articles on tetanus and shock and haemorrhage, but the book is essentially a practical guide to operative surgery. The text is written in German and lavishly illustrated by line drawings a type of illustration which is particularly suitable for works of this character and could be more often used with advantage in English textbooks.

For the most part the pen and ink sketches interspersed among the lines of text are accurate but Fig 10 page 20 shows the cervicofacial division of the facial nerve at too high a level and an incision at the angle of the jaw which would almost certainly divide it. Although facio hypoglossal and facio spinal accessory anastomosis are briefly mentioned in the section on facial palsy correction of the condition by fascial slings is the only method illustrated. A relatively long article on the treatment of trigeminal neuralgia emphasizes electrocoagulation of the gasserian ganglion, a procedure widely popular on the Continent but not in favour in this country. Methods of injecting the ganglion are illustrated but not the surgical approach to the root or tract. The sections on intestinal and genito urinary surgery are perhaps the fullest and best from which we suspect that here may lie the chief interest of the *Privatdozent*. Figs 141, p 446 and 142, p 449 are identical and there would appear to be no need for the repetition. The least elaborated part of the book is that dealing with the surgery of the nervous system, particularly in comparison with the detail devoted to other systems. On the whole the field of surgery is fairly well and evenly covered and as a textbook for students and practitioners it may be said to live up to its title.

PHYSICAL METHODS IN PSYCHIATRY

Shock Treatments and other Somatic Procedures in Psychiatry By Lothar B Kalinowsky, M.D., and Paul H Hoch, M.D. Foreword by Nolan D C Lewis M.D. (Pp 294 21s) London William Heinemann Medical Books 1946

This book by American authors covers the same ground as the much smaller book in which Sargent and Slater two years ago presented the new physical methods of treatment in psychiatry. Treatment by insulin coma and by artificially induced convulsions—still unfortunately misnamed shock treatments—are discussed in great detail. Other physical procedures are recorded in a more perfunctory manner the chapter on prefrontal leucotomy obviously suffers from the limited personal experience of the authors. The introduction of physical methods on a purely empirical basis has provoked not only many fairly well substantiated claims of success but also a flood of theoretical papers—many of them absurd or fantastic.

Unfortunately the authors do not provide much guidance through the international literary jungle catalogued in 37 pages of bibliography. They have much personal experience of the two main therapeutic methods and are critical in evaluating their own results but they frequently succumb to obsolete or hypothetical interpretations, and in presenting the techniques they put the unessential and fanciful side by side with the important and practical. It is too often left to the reader to sift the chaff from the wheat and the book is therefore unsuited to the beginner. The more experienced student will find it a serviceable compilation of facts but will look in vain for a leading idea behind the review of opinions. Even in the concluding chapter on theories the authors do not risk adopting a theory of their own and carefully avoid any partiality.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

1946 Year Book of General Surgery Edited by E A Grahert A.B., M.D. (Pp 679 21s) London H K Lewis 1947

Penicillin in acute appendicitis is discussed and there are articles on the surgical significance of accessory spleens, cerebral abscess and peritoneal or skin grafts fixed with fibrin to prevent leakage after intestinal anastomosis.

The Irish Medical Directory Ninth edition (Pp 358 15s 6d) Dublin Parkside Press 1946

This directory includes articles on penicillin and sulphonamides in surgery.

Charles Edouard Brown Sequard By J M D Olmsted M.A., Ph.D. D.Sc. (Pp 253 \$3.00) Baltimore Johns Hopkins Press 1946

Three biographical lectures on the great neurologist with a bibliography in English.

Die Hormonalen Aspekte Des Fortpflanzungsprozesses By Dr Jules Samuels (Pp 152 No price) Amsterdam Holdert 1946

An account of the relation between hormones and the reproductive cells in German with an English summary.

Medicaments et Medications By H Harnot (Pp 133 No price) Paris Presses Universitaires de France 1947

A short account of materia medica with a chapter on physiotherapy.

Who's Who in Parliament Compiled by Carol Bunker (Pp 176 6s paper covered 7s 6d cloth covered) London St Botolph Publishing Company 1947

Summarized biographical details of members of the present Parliament.

Total War at Haverington By Josephine Bull (Pp 336 10s 6d) London Longmans, Green 1947

A novel whose setting is an imaginary small town in the Thames valley in wartime.

Rezeptierkunde By Prof T Gordonoff (Pp 112 7.50 Swiss francs) Berne Medizinischer Verlag Hans Huber 1947

A short guide to the writing and compounding of prescriptions.

For Doctors Only By Hugh Selwyn (Pp 64 5s) Ipswich Harrison 1947

An amusing account of crises in medical practice.

The Middlesex Hospital Medical School Collected Papers Papers on a variety of topics from the Middlesex Hospital.

Psychiatric Interviews with Children By various contributors Edited by Helen L Witmer (Pp 443 25s 6d) London Geoffrey Cumberlege New York The Commonwealth Fund 1946

Collected records of psychiatric treatment of children in American child guidance clinics with comments by the editor. Intended for students and practitioners of child psychiatry.

Health Insurance in the United States By N Sinai, Dr P H O W Anderson and M L Dollar (Pp 115 8s 6d) New York The Commonwealth Fund 1946

A discussion of the history and organization of voluntary health insurance in the United States.

Health Reform in New Zealand By Douglas Robb M.D. Ch.M., F.R.C.S., F.R.A.C.S. (Pp 103 No price) London Whitcombe and Tombs 1947

An account of the public health services in New Zealand, with suggestions for their improvement.

The Fighting Irish Doctor By E F St John Lyburn B.Ch. BAO M.B. (Pp 199 8s 6d) Dublin Morris 1947

An autobiography by a doctor who is a fighter with gloves and with words.

The Earth's Green Carpet By Louise E Howard (Pp 219 8s 6d) London Faber and Faber 1947

A simple exposition of Sir Albert Howard's ideas on agriculture by his wife with particular reference to soil fertility.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY MARCH 29 1947

BRITISH WARTIME INVESTIGATIONS OF
TYPHUS

Louse-borne typhus has in the past often been one of the most dreaded accompaniments of war. In 1938 it had already appeared in Spain as a sequel to the civil war. It is therefore not surprising that early in the war of 1939-45 organizations were set up both in the USA and in Great Britain to inquire into the best means of preventing and treating a disease which might so readily have caused havoc throughout Europe. In Britain a team of workers drawn from the staff of the National Institute for Medical Research and from the personnel of the R A M C carried out extensive researches in the laboratory and in the field.¹ While the war continued much of this work was naturally regarded as highly secret, and only now has it been possible to publish a comprehensive account of it. The increased efficacy of rickettsial vaccines, which, though they may not always prevent infection undoubtedly decrease the severity of the disease, and the immense value of the newer insecticides in destroying lice are already well known. Less has been heard of the energetic efforts made to find chemotherapeutic remedies for rickettsial infections, which are scarcely affected by antibiotics or by the better-known sulphonamides.

A convenient method of testing the antirickettsial activity of large numbers of chemical compounds was to inoculate mice intranasally with dilute suspensions of typhus rickettsiae, such mice when killed seven days later show discrete greyish lesions on the surface of their lungs, and these lesions can be counted. Intranasal inoculation of mice is a highly dangerous proceeding to laboratory workers, unless special precautions are taken. Indeed, following infection of workers in other laboratories in this country, all five of those engaged in using this method at Hampstead contracted an infection fortunately not with epidemic but with murine typhus. Those who have suffered from a murine infection, however, will agree that it is not entirely a pleasant experience: it does, however, give a solid immunity against louse borne infection. A special inoculation box was designed at the National Institute for Medical Research (van den Ende²) for the safer handling of mice and other animals used for intranasal inoculation, and in the ensuing two and a half years after 1943 only one other laboratory infection occurred though many fresh workers assisted in typhus studies. At the Army Emergency Vaccine Laboratory at Everleigh nine infections occurred before the introduction of a satisfactory inoculation box none afterwards.

When the chemotherapeutic experiments were carried out on mice infected intranasally with rickettsiae the maximal dose for each drug was determined by intraperitoneal injection, and that dose was then administered in 0.5 ml of saline daily for four days, the first intraperitoneal dose being given two hours before infection with typhus. In all, some 238 drugs were tested for activity against experimental typhus infection in mice. Results were completely negative till V 147 (*p*-sulphonamidobenzamidine hydrochloride) was reached, this compound strikingly reduced the numbers of lesions on the lungs of mice. It was found, however, that V 147 was very rapidly excreted and better curative results were achieved by giving it twice daily. When this was done it became possible to suppress entirely the development of lesions in mice given a dose of rickettsiae producing some 150 foci in the lungs of untreated mice. In later tests, including a series of compounds related to V 147, the drugs were injected six times in all once before infecting the mice twice daily on each of the two following days, and once on the morning of the third following day.

Of twelve related compounds, V 186 *p*-sulphonamidobenzamidoxime hydrochloride, the amidoxime corresponding to V 147, was found to be equal to it in activity or perhaps a little better.

Any considerable modification in the molecule invariably destroyed chemotherapeutic activity (Andrewes, King, and Walker³). V 186 did not appear to have any antirickettsial activity *in vitro*, but in the mouse inoculated intranasally, it showed activity in a dose of 2 mg twice daily, or one-twelfth of the maximum tolerated dose of 24 mg. Subcutaneous injections of the drug gave much the same results as intraperitoneal injections, the compound could also be mixed in the food, when about the same dosage was effective as with parenteral injections, provided the compound was given in the food in two divided instalments. Most activity was observed when V 186 or V 147 were given before or soon after infection, but a definite action was still produced when treatment was delayed for 42 hours after infection. The two compounds were effective against both murine and epidemic strains of rickettsiae. In order to test the activity of these compounds in man a team left for North Africa and Naples where typhus was epidemic. To assess correctly the chemotherapeutic activity of the two compounds a thorough clinical and pathological study of the disease was necessary in patients receiving only the usual supportive treatment. One section of the report therefore gives a full account, with illustrative cases, of epidemic typhus as it was seen during the war years in Algiers and Naples. This account of the clinical symptoms and pathological changes is of considerable value apart from the chemotherapeutic trials which rendered it necessary.

It was an intense disappointment when it became evident that neither compound had any specific action in modifying the course of the disease in man. The reason why

¹ Van den Ende M, Stuart Harris C H, Fulton F, Niven J S F, Andrewes C H, Bege A M, Elford W J, Gleeson White M H, Hawley W L, Mills K C, Hamilton F and Thomas C C. Chemotherapeutic and Other Studies of Typhus. Med Res Cncl Sp Rep Ser No 265 London H M Stationery Office 1946.

³ Brit J Pharmacol 1946 1 15

compounds should be active in one species and inactive in another is of considerable theoretical interest but is so far unexplained. A most striking example is optochin, ethylhydrocupreine, which is quite active in treating pneumococcal infections in mice but is useless in pneumonia in man. It is noticeable that in mice neither V 147 nor V 186 was inhibited by *p* aminobenzoic acid, nor, when tested by the intranasal method, was it possible to show that *p*-aminobenzoic acid had any activity against rickettsiae. It was, however, possible to confirm the observations of Snyder Maier, and Anderson⁴ that *p*-aminobenzoic acid has some action when given by mouth to typhus-infected mice. This compound has now been shown to have an inhibitory effect on many species of rickettsiae, while in man it is of value in many varieties of rickettsial infection.

The last three sections of the report deal with the elaboration of a quantitative test for neutralizing antibodies against typhus rickettsiae, a comparison of typhus vaccines in the laboratory, and a study of the antigenic structure of murine and epidemic typhus rickettsiae. The quantitative test for rickettsial antibodies makes use of the number of foci produced in the mouse lung when mice are inoculated intranasally with rickettsial suspensions mixed with progressive dilutions of anti-serum. Qualitatively the intranasal test gives similar results to the intradermal rabbit test devised by Giroud⁵ in 1938, but quantitatively the mouse test is the more satisfactory. For assessing the potency of typhus vaccines it was concluded that the most satisfactory test is the capacity of the vaccine to protect mice against the toxicity of rickettsiae injected intravenously. Studies on the antigenic structure of murine and epidemic typhus rickettsiae show that both murine and epidemic strains have surface antigens, some of which are similar. Unfortunately no fresh light is thrown on the question, so important for an accurate knowledge of the epidemiology of typhus, whether murine typhus rickettsiae can ever so mutate that their antigens become identical with those of epidemic strains. The OX 19 antibody of rabbit rickettsial antisera, however, is shown to be quite distinct from the antibodies produced by the undegraded surface antigens of the rickettsiae: it is apparently a fraction of the group of antibodies which reacts with rickettsiae degraded by boiling.

NUTRITION AND WOUNDS

The term "wound phthisis" has been aptly used to describe the wasting which accompanies sepsis. Cuthbertson^{6,7} has drawn attention to the nature and the magnitude of the nutritional problem in these cases and particularly in the patient with extensive burns. In a recent paper Dunphy, Hoerr, Dimmler, and White⁸ have described the post-operative regime at the Fifth General Hospital of the United States Army for battle casualties of the Normandy campaign who had abdominal wounds of a character which rendered evacuation to the United Kingdom impossible. Their patients were selected for transfer to a special unit because of their poor general condition, and they represent

the more complicated cases of a total of about 150. All of the 16 cases treated had multiple injuries and had varying degrees of anaemia and hypoproteinaemia when they were received. Retroperitoneal, peritoneal, or wound infection was a major complication in 12 cases and was the cause of the two deaths in the group, one from rapidly progressing peritonitis and the other from extensive retroperitoneal abscesses. Intestinal obstruction developed in 11 cases and required a second operation in two of them. There were 7 cases of jaundice.

It must be recognized that the perfect parenteral food substitute has not yet been found. The main difficulty is to secure an adequate calorie intake which will prevent amino acids which are necessary for tissue building from being deflected to meet energy requirements. In general Dunphy and his colleagues employed 500 ml physiological saline to replace salt loss, with 2,500 ml 5% glucose in distilled water to replace the loss of water and to supply some 500 calories. Variable volumes of 5% glucose in saline (200 calories per litre) replaced the salt and fluid loss from gastric suction, ileostomy, fistula, etc., and 1,000 ml of plasma or whole blood (all whole blood if the haemoglobin was below 80%) provided some 50 g protein (200 calories). Liver extract and some vitamins were also given. This regime was not ideal but was dictated by the available supplies. (This type of case is one which should respond well to a safe and nutritionally adequate preparation of glucose and amino acids provided it could be administered in not too large a volume, though the report by Madden, Woods, Shull and Whipple⁹ that partial hydrolysates of protein are more efficient nutritionally than completely hydrolysed proteins or amino-acids makes further investigation necessary.) The fluids described were additional to the whole blood or plasma given pre-operatively to treat blood and fluid loss. Owing to the impracticability of repeating intravenous injections of concentrated solutions of glucose, it was necessary to rely on small supplemental oral feeds, usually in the form of sweetened milk, which were often begun before all evidence of peritonitis or intraperitoneal infection had subsided. These American workers agree that whenever possible matched blood or type-specific plasma should be transfused. Although Type O whole blood and plasma were used, there was some evidence that a haemolytic anaemia might be produced if high-titre blood was employed. Their regime appears effectively to have restored the levels of haemoglobin and serum protein in the patients in an average of seven to ten days.

The excessive catabolism of body protein which normally follows moderate or severe injuries may lead to a severe degree of malnutrition, particularly if there is infection. Residual abscesses must therefore be promptly drained. This recent experience emphasizes that external fistulae add a serious burden to the patient with abdominal wounds and that open ileostomies should be avoided where possible. On the other hand associated infection is even more deleterious to the patient's condition, for when the infection is controlled the fistula generally heals.

MARROW BIOPSY IN DIAGNOSIS

It is recorded that Schilling once rebuked a questioner who had asked about changes in the bone-marrow with the words, "Sir, I am a peripheral haematologist." The day of the peripheral haematologist has closed, and bone-marrow examination is now as commonplace as blood counts were twenty-five years ago, but the search for a completely satisfactory technique continues. Sternal puncture with examination of films made from the aspirated material and stained by one of the Romanowsky methods is the routine, but its shortcomings have always been obvious. It does not give any exact indication of the bone-marrow's cellularity, it shows no changes in the marrow's architecture, and the aspirated fluid consists of bone-marrow and blood mixed in proportions varying roughly with the volume withdrawn. For these reasons Seyfarth's method of sternal trephining has always had its adherents. It is, however, a far more ambitious procedure than sternal puncture, entailing considerable discomfort to the patient and all the panoply of a surgical operation.

A method is required which will provide material for fixed sections of bone-marrow as well as for films which allow study of cytological detail, while subjecting the patient to no more inconvenience than sternal puncture. Many haematologists have been accustomed, after making films, to allow the residue of the aspirated material to clot. This clot is fixed and embedded, in sections cut from it fragments of intact bone-marrow tissue can be seen. Ampino and Penati (1935) were the pioneers of this method, modifications of which were used by Rohr (1937) and many others. Such sections are not always satisfactory and the fragments of marrow may be scanty. Cappell, Hutchison, and Smith describe a technique in this number of the *Journal* which has the advantages of concentrating the fragments of bone-marrow obtained by sternal aspiration, while removing the admixed blood. It merits a careful trial by all interested in marrow biopsy. A possible disadvantage is the need for aspirating 0.5-1.0 ml of fluid such a volume results in films of low cellularity which may be tedious to examine. Nevertheless their method is clearly superior to those in common use, and perhaps at last the answer to the haematologist's prayer for a means of combining the advantages of sternal trephining with those of sternal puncture.

SURGICAL EXPLORATION OF THE ORBIT

Space-occupying lesions of the orbit usually present an awkward surgical problem, partly because of difficulties in diagnosis and partly because a decision on the best surgical approach is not always easy. It is true that a pre-operative diagnosis of the nature of a tumour is often possible, but it frequently happens that despite the fullest exploitation of clinical and laboratory methods, including a search for signs of systemic disease (as in the case of neurofibromatosis described by H. B. Stallard in this issue of the *Journal*), stereoscopic radiography (by demonstrating the tumour itself in shadow or revealing thickening, rarefactions or dilatations of the orbital wall), piezometry to determine its consistency, and rhinological, nasopharyngeal, and neurological examination the diagnosis can be only tentative and must wait for surgical exploration. The surgical approach chosen should depend on the location—or the probable location—of the tumour. Apart from radiographic findings and the easy case where the tumour is anteriorly situated and is itself palpable, the direction of the proptosis, the degree of immobility, and the visual disturbances may provide valuable clues. As a general rule tumours at the apex of the orbit or within the muscle-cone produce an axial proptosis with retention of ocular

movements and early ophthalmoscopic and visual disturbances, tumours outside this or associated with the orbital walls or encroaching upon them from outside are associated with eccentric proptosis, restricted mobility particularly in one direction, and retention of vision. As a general rule, also, early immobility of the eye is suggestive of malignancy, while marked proptosis with retained mobility is more characteristic of benign growths.

In the literature of the last fifteen years there has arisen a considerable controversy as to the best surgical approach for lesions of this type, and claims have been made for the universal applicability of one or other technique. This has arisen since advances in cranial surgery have rendered the transfrontal approach through the cranial cavity with removal of the orbital roof a relatively safe procedure, it has been popularized particularly in America in the expert hands of such surgeons as Naffziger and Dandy. Nothing however, could be more unwise than to press the claim of universality for any single technique in a problem of this type. Five are available, and for all five there is a place. Lateral osteoplastic orbitotomy (Kronlein's operation), whereby the lateral bony wall is temporarily removed, is an excellent operation provided the tumour is entirely intraorbital and is laterally situated, it is frequently unnecessary if the tumour is small, but is probably most advisable when its size and location are unknown. The transfrontal route probably provides the freest access to the apex of the orbit, and is certainly the method of choice whenever an intracranial extension is suspected or feared (as in the common meningioma). On the other hand, subperiosteal tumours or those invading the orbit from the paranasal sinuses are usually best dealt with by entering the subperiosteal space through an incision parallel to the superior orbital margin and displacing the orbital contents (anterior external orbitotomy). Through the same incision, by displacement of the globe and orbital contents and incision of the periosteum, the majority of tumours of the soft tissues of the upper and inner parts of the orbit outside the muscle cone can be removed after digital exploration. An anterior transconjunctival route either nasally or temporally, wherein the conjunctiva is incised at the fornices to the vertical meridian above and below, a canthotomy made, the appropriate horizontal rectus temporarily detached, and the globe strongly rotated, provides access back as far as the optic nerve. Finally, when the nasal sinuses are also involved the most effective approach may be made through them. In the choice each case should be considered individually and that route chosen which is most appropriate to the lesion in question and best adapted to the technique of the surgeon.

TREATMENT OF DELINQUENCY

Fifty years ago Samuel Butler's suggestion that society would eventually consign its criminals to hospital and its sick to prison was considered outrageously paradoxical and at the beginning of Queen Victoria's reign more than 200 offences were punishable by death. About thirty-five years ago Norwood East started psychotherapeutic interviews with adolescent and adult men charged with attempting suicide and other offences. To-day the scientific investigation and treatment of the causes of delinquency are still in the pioneering stage, though the attention devoted to it both conforms with the present trend of social legislation and follows the far older tradition of humanitarianism. There are various causes of the comparative neglect that this branch of study suffers from. As Dr Edward Glover points out on page 421 of this issue, the layman often adopts an "attitude of moral reprobation" towards the criminal, and the depth of feeling behind it is sometimes

revealed in discussions and letters to the Press on such topics as capital and corporal punishment. Man jealously guards his social relationships and reacts with instinctive violence to attempts at their disruption, just as ants will seize and kill an intruder from a neighbouring colony. The attitude of society as a whole to a problem cannot be dissociated from its investigation, particularly in the early stages, if only for the reason that pioneers must often rely on voluntary financial support.

The Institute for the Scientific Treatment of Delinquency was founded after publication of the MRC report¹ in 1932 on the psychology of delinquency. Grace Pailthorpe then expressed the basic problem in these words: "The so-called criminal is not a person who suddenly crystallizes out as a criminal. His asocial behaviour is traceable back to his childhood days." The criminal's attitude towards society is regarded as a development of his childhood attitude towards his family. The surprising feature of Dr Glover's experience at the Institute is that the results, in skilled hands, of treating psychopathic delinquents are more successful than those obtained with neurotic delinquents, and "even the 'old lag' is more amenable to psychological handling than the schizoid character."

It is to be hoped that the support from the general public asked for in a letter to *The Times* (March 12) from the Archbishop of Canterbury, Lord Horder, Sir Cyril Burt, Dr Glover, and Mr John Watson will be forthcoming. The work carried out at the Institute and elsewhere has established the value of psychotherapy for delinquents. In 1939 Norwood East and Hubert² wrote: "Psychotherapy as an adjunct to an ordinary prison sentence appears to be effective in preventing, or in reducing the chance of, future antisocial behaviour provided the cases are carefully selected." It should no longer be necessary to have to appeal for funds to carry on work of proved worth—work, moreover, that should diminish the country's expenditure on criminals.

REACTION TO OILS AND FATS

The parenteral introduction of oily or fatty material of animal or mineral origin always provokes a typical and severe reaction. Pathologists are most familiar with this when sebaceous or dermoid cysts rupture, and in fat necrosis there is an intense giant-cell reaction around crystals, or macrophages which appear foamy in paraffin sections. Such a reaction, however, is often a sequence to suppuration, instead of a complete resolution. Lipoid substances appear to be concentrated and cause a similar reaction. This is particularly the case in the lung. In the neighbourhood of new growths and of bronchiectatic cavities a condition once wrongly described as "unresolved pneumonia" is commonly found: the alveoli are packed with foam cells as a rule without foreign-body giant cell reaction.

Oils and fats are often deliberately introduced for therapeutic purposes, by no means always with harmful results. Penicillin and other drugs are to-day administered in wax and vegetable oils, and for radiographic purposes iodized poppy-seed oil is introduced into the bronchus, apparently without any ill result, although the oil remains for many months in the bronchi. On the other hand, mineral oils injected subcutaneously cause severe reactions as many beauty seekers know to their cost. Lanoline injected into the peritoneum produces a foreign-body-reaction tumour within a few days. And there is no doubt that the inhalation of mineral oils may induce severe and sometimes fatal

reactions in the lung—a condition usually described as lipoid pneumonia. Many oily medicaments for treating sinusitis are on the market, and their use is probably wide. They are bland, as the rather eighteenth-century terminology has it, and cause no cough reflex. The majority of recorded cases of lipoid pneumonia have been, however, in patients who were very young, very old, comatose, or with paralysis of the muscles of deglutition. Paterson discovered 8 cases in 813 necropsies at University College Hospital, London, a surprisingly large number in view of the small total number in the literature. R. E. Rewell contributes in this number a further case, which is in many ways unusual. The patient was a previously healthy young woman, and there was no history of administration of oily substances in any form. There are undoubtedly cells containing macrophages in the alveoli, and these contain fat. The nodules in the spleen and liver are also most exceptional in lipoid pneumonia. As the author says, however, the case is a pretty problem in differential diagnosis. Some pathologists might prefer to look upon the condition as granulomatous and the lipoid-containing cells as representing the non-specific reaction, commonly seen in the lung, to which we have referred.

Though vegetable oils are inert in the human organism it is well to remember that animal fats even of homologous origin cause foreign-body reaction. Mineral oils, being emulsified, are exceedingly dangerous in the wrong place, and especially in the lung.

A CONTRIBUTION TO THE DAIN FUND

Insurance practitioners throughout the country will after April 1 receive something over £3,500,000 as a final settlement for the year 1946. In stating this fact in the *Supplement* of March 15 Drs H. M. Golding and W. Woolley proposed that a small share of this "windfall" should be devoted to charitable purposes. They recorded a resolution unanimously passed by the Bristol Local Medical and Panel Committee, the gist of which was that all insurance practitioners should give to the Dain Fund 1% of the lump sum they will receive in settlement of the final increase of 3s for the year 1946. This proposal was backed up in the *Supplement* of March 22 by Dr Janet Aitken as Chairman of the Charities Committee of the B.M.A. Dr Aitken pointed out that the resources of the Dain Fund are now strained and that the trustees have recently been unable to give help where help was needed. Even though times are hard and expenses heavy it is hoped that insurance practitioners will express in this desirable manner their gratitude to the Insurance Acts Committee for securing this increase in the capitation fee.

The Dain Fund, it may be recalled, was inaugurated in 1936 in honour of Dr H. Guy Dain for his outstanding services to the profession. The Fund was completed in 1939 when it amounted to over £4,500, but owing to the war it was not presented until the Panel Conference Dinner in November of last year. Dr Dain had already intimated that he wished the fund to be devoted to the education of doctors' sons and daughters in need of financial help. The trustees reported last October that 8 out of 18 applicants had been assisted with substantial grants, but lack of resources had compelled them to forgo help to others in only slightly less urgent need. Those who wish to follow the excellent example of Bristol should send their contributions to the Secretary of the Dain Fund at B.M.A. House, Tavistock Square, London, W.C.1.

We announce with regret the death on March 21 of Sir Joseph Barcroft, F.R.S., formerly professor of physiology at Cambridge University.

THE INVESTIGATION AND TREATMENT OF DELINQUENCY

By

EDWARD GLOVER, MD

Director of the Psychopathic Clinic Chairman of the Scientific Committee of the Institute for the Scientific Treatment of Delinquency

Looking back over the development of clinical psychology during the past quarter of a century it is now perfectly clear that our understanding of ego-disorders has lagged woefully behind that of the neuroses and other varieties of encapsulated symptom formation using this term to convey that a given symptom does not infiltrate the normal layers of the patient's ego. Freud was often reproached for inferring the nature of normal function from a study of the abnormal, but we now know that the normal ego is infinitely more difficult to comprehend and consequently to modify, than those abnormal formations which may, as it were, attach themselves to it.

But granted that the ego and its disorders are more refractory to analysis than the disorders of instinct it is still remarkable that the particular group of ego-disorders described as delinquent has been the last to stimulate the curiosity of the psychopathologist. Actually we know more about the mechanisms of the psychoses than we do of the causes of crime. No doubt this neglect is due in part to the same deep prejudices that are responsible for the attitude of moral reprobation with which most laymen greet criminal behaviour, for the view, in short that sinful conduct must not be 'condoned' by the discovery that it is frequently a sign of illness. Anyhow, it is significant that in psychiatric clinics the diagnosis and treatment of delinquency is still regarded as rather an esoteric interest. Even in child guidance clinics where it is freely recognized that delinquent behaviour is a common sign of abnormal development it is not yet fully appreciated that this group of ego disorders deserves and requires the attention of specially trained investigators.

It was this latter consideration that led to the formation of the Institute for the Scientific Treatment of Delinquency, a title which may now appear cumbersome and tendentious but at the time described precisely a current need. Indeed there seems to be little question that as medical psychology expands it will inevitably create a number of specialties corresponding to the specialties of organic medicine. Each of these will be concerned with the investigation and treatment of conditions that are at present merely regarded as types of mental disorder.

Already the work of the Institute has indicated the focal point at which the energies of a future generation of trained workers must be directed. For although study of representative samples of case material has established the incidence of different types of delinquency—e.g. neurotic, psychotic, psychopathic, mentally defective, organic etc.—it is in the psychopathic group that most of the unresolved problems of delinquency lie. Naturally the term psychopathy like its congener schizophrenia is one of these omnibus labels that serve to conceal a regrettable lack of understanding. But like schizophrenia psychopathy represents a well defined clinical group with recognizable subdivisions. The delinquent psychopath, for example is frequently also a sexual pervert even if this abnormality has not been marked enough to lead to the commission of detectable sexual offences. Admittedly the constitution of delinquent groups is influenced by the penal codes sanctioned by the community. A large proportion of the cases seen at the Institute are charged with exhibitionism and homosexual offences. But even excluding such cases the proportion of delinquents diagnosed as psychopathic is a high one. It is no exaggeration to say that the investigation of psychopathy will shed more light on the normal development of the ego and of that remarkable instrument the super-ego (unconscious conscience) than any other clinical entity with the possible exceptions of schizophrenia and manic-depression.

Equal importance attaches to the therapeutic experience gathered at the Institute. In some respects the results obtained are contrary to psychotherapeutic expectation. It had always

been supposed that neurotic types of delinquency would respond readily and allowing for the fact that the patient commences his treatment in a state of 'negative transference' this supposition has proved well founded. The contrary assumption—namely that the psychopathic delinquent would be harder to treat—has not proved to be accurate. He certainly calls for more skilled handling but given this skill, the results are even more striking than in neurotic types. Even without any formal attempt at psychotherapy the effect of mobilizing the interest of a number of "supporting figures (psychologist, psychiatrist, social worker, probation officer, teacher, employer, foster-parent etc.) is quite remarkable. Allowing for the fact that neurotic types will also improve under such conditions, still the psychopath clearly demonstrates his amenability to manipulation of his psychic situation. Even the 'old lag' is more amenable to psychological handling than the schizoid character.

It is clear that progress in the field of delinquency calls for research on every variety of delinquent or pre-delinquent conduct. And this is not within the scope of the ordinary psychiatric clinic. The case for special centres for the investigation and treatment of delinquency has been proved up to the hilt. Only when a number of centres or special departments are established throughout the country and linked up with an international organization can we hope to put the problem of anti-social conduct on a thoroughly scientific basis. Only in this way can we hope to secure full recognition of the authority of medical psychology by the judiciary.

Interestingly enough the difficulties that beset the London Institute have not been clinical difficulties. For reasons already indicated projects for treating delinquents have little popular appeal yet like all pioneer efforts, they are bound to depend in the first instance on voluntary support. Even with the most rigid of State organizations pioneer work on social problems is likely to come from extramural centres. Despite exiguous finances and consequent shortage of staff the Institute survived the war. It is to be hoped that it will survive the austerities of peace.

LIVERPOOL MEDICAL SCHOOL

In 1847 the annual report of Liverpool Royal Infirmary recorded the completion of a medical school. So began the Royal Infirmary School of Medicine, the direct descendant of the present medical faculty of the University of Liverpool. Medical teaching had been going on in Liverpool some time before 1847. There is a record of lectures given in 1811 and it seems reasonable to suppose that at least a large number of the 634 candidates examined by the medical board of the Infirmary between 1789 and 1807 were trained in the city. Liverpool was involved in body-snatching before the Anatomy Act of 1832 and cadavers were sent from there to the medical schools in Edinburgh.

Students at the Liverpool Infirmary Medical School took the examinations of London University, and the University College Liverpool, was created because in 1876 practical physics became compulsory for the London first M.B. examination. The need for an endowment for a chair in physics led to the formation of the University College which in 1903 was incorporated as the University of Liverpool. In 1865 the number of students at the Liverpool medical school was 28. There are now 528 undergraduates and 304 postgraduate students. Liverpool, true to the traditions of Hugh Owen Thomas and Sir Robert Jones has established a specialist postgraduate degree in orthopaedics; there are also courses for the D.P.H. and mastership in radiology.

Notable names connected with the Liverpool medical school include W. H. Duncan, the world's first medical officer of health who was lecturer in medical jurisprudence at Liverpool and Sir Charles Sherrington. Frank Thomas Paul, inventor of Paul's tube, was dean of the medical faculty for seven years. The present Dean is Prof. T. B. Davie, M.D., F.R.C.P.

A Gerontological Unit under Dr. N. Shock is to investigate kidney diseases in Baltimore City Hospital, USA. A group of healthy subjects aged from 30 to 90 will undergo tests at intervals of 1 to 5 years.

A Gift to the RMBF

SIR,—I am anxious to acknowledge through your columns the receipt of a donation of £647 18s 10d from Messrs Burroughs Wellcome and Co (the Wellcome Foundation Ltd). This gift has been made by the very kind and generous thought of their directors in transferring the payments for the 1946 issue of the Wellcome Medical Diary to this fund. On behalf of my committee I desire to express our warmest thanks to Messrs Burroughs Wellcome and Co and also to assure all who made payments for the diary that this gift of £647 18s 10d will be the means of bringing some extra measure of comfort and ease to many of our beneficiaries—I am, etc,

The "Costoclavicular Syndrome"

SIR—The instructive article by Prof E D Telford and Mr S Mottershead (March 15, p 325) on the costoclavicular syndrome prompts me to mention a cause of paraesthesia in the arms and hands of middle aged men to which I have not seen any reference. Two cases have come to my notice in the last few years. The paraesthesia is caused by wearing a shirt of thick material with the sleeves rolled up to the axilla. From the causation it will be apparent that the symptoms are worse in cold weather and out of doors—i.e., when a thick overcoat is worn in addition. The mechanism is similar to that of the fakir's trick of stuffing a handkerchief into his armpit and stopping his radial pulse at will by pressing his arm closely to his side.

An interesting point in my two cases is that neither man would wear his shirt sleeves unrolled. When seen a year or so later they were free from symptoms, but each informed me that he could not bear long shirt sleeves and had cut them off—I am, etc,

Preston Lanes

R SLATER

SIR—Amidst a mass of inconclusive literature on pain in the arm the article by Prof E D Telford and Mr S Mottershead (March 15, p 325) stands as a beacon of clear thinking founded on careful experiment and is only equalled by the summary of the literature in your editorial. It would appear from these articles that the key to the condition lies in the spasm of the scalene muscles, and it has long been held by the osteopaths that this spasm is initiated reflexly from a subluxed cervical joint. The strain of the cervical joint is maintained by, and is secondary to, a subluxation in the upper dorsal area. This may result from single or multiple trauma with the neck in side-bending rotation, such as may follow from a blow, or lifting bulky articles off a shelf above the head.

Manipulation of the cervical area frequently relieves the symptoms, but it is essential to obtain good movement of the upper dorsal subluxation in order to produce a permanent result. While a compression of the median nerve at the wrist may be a factor in certain cases it is felt that most of these lesions are central in origin—I am, etc

W HARGRAVE-WILSON

Spirillum (Abacterial) Pyuria

SIR—I was very interested to note in the article on 'Abacterial Pyuria' by Drs W E Coutts and R Vargas-Zalazar (Dec 28, 1946, p 982) that a spirillum had been found in the centrifuged urinary deposit of the five cases presented.

During the last month I have had the opportunity of seeing a further case of abacterial pyuria. A centrifuged sample of the urine was examined under dark-ground illumination and was seen to contain numerous spirillum-like bodies 5-10 per field, among the pus cells, length 5 μ all of a similar shape, containing one or two regular curves along their length. This spirillum was also observed by a medical colleague and our sergeant special treatment orderly. The patient had no obvious dental sepsis or infected teeth. There was no radiological evidence of

a tuberculous focus in either lungs or renal tract. An intra venous pyelogram revealed no abnormality of the renal tract. Treatment was commenced with the following course of neoarsphenamine on Feb 7 9, 11, 0.3 g NAB and on Feb 19, 0.6 g NAB (total, 1.5 g). There was an immediate diminution in the urinary frequency. After the second NAB the urinary frequency was normal. On Feb 17 the urine had almost cleared and on Feb 19 the urine was perfectly clear—I am, etc,

Congenital Malaria

SIR,—With reference to the correspondence in the columns of the *British Medical Journal* during the early part of 1946 concerning congenital malaria I should like to draw your attention to my article in the October–November, 1942, issue of the *East African Medical Journal*, 19 223 and 247, in which I gave figures of infants who were found to be suffering from malaria at birth. The blood was taken from the baby's finger on three consecutive days following its birth, and out of 700 patients examined 40 mothers were found to have malaria parasites in the placental blood, and 2 infants.

These figures are by no means so impressive as those quoted by Dr R R McKay in the *East African Medical Journal* in 1933 10, 246, or in a communication published in 1936 entitled 'An Account of an Investigation into Malaria at Dares Salaam,' p 17—I am, etc,

Nairobi Kenya

P G PRESTON

Haematological Heresy

SIR—Unfortunately I have only recently been able to read Dr R R Bomford's most stimulating article (Dec 28 1946 p 996) and I wonder if I might be permitted to make a few inexperienced comments. Should the haemosiderosis, the hyperbilirubinaemia and urobilinuria, and the histological evidence of active phagocytosis be regarded as conclusive proof of haemolysis? The latter surely can be found in the normal subject if it is looked for. The others could, I think, be adequately explained by the excess of formed and perhaps partially formed, haemoglobin now having "nowhere to go" because of the maturation arrest at the haemoglobinizing stage in haematopoiesis. There is seldom an iron lack in pernicious anaemia as in normal erythropoiesis iron is neither excreted nor deposited but enters the haemoglobin molecule. In an erythropoietic upset, however, the iron cannot be utilized and it becomes deposited and increases the iron store. Hence the haemosiderosis.

Hyperbilirubinaemia and urobilinuria go hand in hand and are constant findings in the haemolytic anaemias. Their presence alone, however, does not, I think, justify the haemolytic theory. Again, bearing in mind the fact that there is no deficiency of iron and that there is every stimulus for the formation of haemoglobin from the tissue iron, anaemia consequent upon the low red cell count, it is not difficult to imagine non-utilized haemoglobin being (a) broken down to haematin and hence to bilirubin, or (b) itself having a maturation arrest in its synthesis, and possibly the porphyrin III being diverted into bilirubin or some such similar pathological metabolism occurring. This would still explain the raised excretion of porphyrin in pernicious anaemia, as the stimulus for haemoglobin formation is still there and the synthesis, or para-synthesis still occurs—perhaps even in excess. Nevertheless the porphyrins are being utilized and therefore the faecal coproporphyrin I would be raised if the call for haemoglobin is increased.

Another aspect of the hyperbilirubinaemia is the question of liver damage. I think Rich excised somewhere in the region of 90% of a normal dog's liver before he managed to produce jaundice. Reversing this statement it would mean that the destruction of red cells would need to be nine times greater than normal at least before jaundice developed. The life of a red cell must vary tremendously and Lichtwitz states that it should not be measured in time but in actions—'oxygen carries' as he calls them. It has been stated that an average figure is a "life" of 50 days. Normal destruction would then be roughly 1/50 cell per day, or in total 100,000 per day. To bring about a jaundiced condition in a haemolytic anaemia, therefore, would require the destruction of 1,000,000 cells per day. I do not know exact figures, but suspect that the blood level is not lowered so acutely as this even in P.A. relapse. The characteristic lack of symptoms in P.A. suggests a insidious lowering. To produce the biochemistry of the jaundice in P.A. it seems that liver damage then might conceivably also play

part Also supporting this statement is the fact that the supposedly very sensitive bilirubin tolerance test as a measure of liver damage, is diminished in pernicious anaemia

In iron deficiency and in Addison's anaemia the red cell fragility is normal or more usually decreased, whereas in the haemolytic type of anaemias it is usually increased—this includes the toxic type of haemolysis, e.g., in lead poisoning

There is one factor not mentioned by Dr Bomford which seems to materially support his argument, and that is the presence of methaemalbuminaemia in pernicious anaemia. It is only formed, so far as is known, from extracorporeal haemoglobin and serum albumin and is therefore supposed to indicate intravascular haemolysis. It is found in all the haemolytic anaemias except acholuric jaundice; its absence there being accounted for by the supposition that in this disease the haemolysis is performed by the reticulo-endothelial system and therefore extravascularly. It might also be pointed out that the methaemalbumin is excreted solely by the liver and that in liver damage it might be retained, but its very presence is pathological, I believe. There is one last simple but apparently significant fact that seems very much in favour of the faulty erythropoiesis theory and that is the almost constant finding of leucopenia and thrombocytopenia in cases of pernicious anaemia in contrast to the opposite state found in the haemolytic anaemias.

Unfortunately being somewhat isolated, I have no means of checking these statements nor of getting them criticized. A practical suggestion, should it not already have been performed which might shed some light on the theory of unused haemoglobin being the source of the excess of bilirubin in the serum etc. might be the determination of serum bilirubin levels and urobilinogen excretion in cases of Addison's anaemia with superimposed iron deficiency—I am, etc

MELF

Principles Governing Nervous Activity

SIR—Prof E. D. Adrian describes (March 8, p. 305) how synaptic delay through multineurone arrangements and after-discharges accounts for 'long lasting central effects' by which the results of an afferent message might be stored indefinitely to influence behaviour for many years to come. Such specialized continued activity over years is incompatible with normal sensory experiences whose residues are known to be dormant (as engrams) until a similar sensory circumstance again occurs. Residua of sensory patterns therefore are not in activity but a structural tissue change such as is afforded by neuroblastosis and growth of capillaries. The neural equivalent of what went on in the mind may be a necessary adjunct for mental development and its expression, but must not (as I have shown, Feb. 8 1938, p. 265) be considered as an actual part of mental phenomena because of absolute differences in the fundamental characteristics of neurone and mental function.

That purposive acts must be moulded by afferent patterns may be simply explained by assuming with some degree of positive evidence that the afferent stimuli cause local changes of lumen of cerebral capillaries which open or close appropriate reflex pathways by influencing threshold values of adjacent neurone groups. Neuronal activity along these open pathways is known to leave a wake of acid and other metabolites which can change the vascular pattern and so cause subsidence of the central disturbance. If the original pattern of afferent stimuli still remained, then the vascular pattern would of course tend to reform.

The signalling of the achievement of purposive acts along afferent pathways as the cause of the subsidence of the central disturbance which is the basis of Prof. Adrian's scheme for investigation involves a decentralization of mental phenomena and seems to me unnecessary since an urge readily disappears without change of pattern of the afferent stimuli, upon the advent of unrelated stronger stimuli.

F. A. PICKWORTH

Rubella and Pregnancy

SIR—I refer to the letter from Dr Robert Sanderson (Feb. 1 p. 199). It is easy for the objective observer to criticize the remedies proposed for illis which have not affected him personally but the objective viewpoint tends, *per se* to be truer representation.

Dr Sanderson saw his grand-daughter afflicted with a deaf-mutism which probably was a consequence of rubella during

the pregnancy of her mother. He advocates abortion of pregnancies during which rubella occurs, as, he understands, "is being done in Australia" (is it being done in Australia?) This suggestion of his must be based on emotion rather than on reason. The figures in your leading article of Nov. 23 1946 (p. 778) indicate that a possible 10% of all rubella pregnancies result in congenitally abnormal children. Has Dr Sanderson any suggestions to make as to how we may discriminate so that the nine out of ten infants who would be born entire may escape the 'massacre of the innocents'? Or does it seem feasible that such diagnosis will ever be attainable? However, granting the discovery of a method which will enable us to identify deaf-mutism or such in the unborn, we now come closer to the basic objection to direct abortion which Dr Sanderson advocates. To quote his letter 'deaf-mutism is such a domestic catastrophe and permanent sorrow that I advocate inducing abortion'.

The root of the problem lies deeper. May I quote 'For those who believe no explanation is necessary, for those who do not believe, none is possible. It is accepted as the result of rational argument by philosophers and theologians of many denominations that direct abortion is murder and is therefore never justifiable. There are many more problems' in relation to the morality of abortion, some whose correct solutions are more difficult of acceptance, than that introduced by the association of rubella in pregnancy with congenital defects. It is for that reason that I ask you to publish this letter suggesting the correct approach ethically to these things: it is the morality of our behaviour which must take precedence over its expediency in such dilemmas which are really only apparent and are not unsolved—I am, etc,

P. O. Seshela N. Rhodesia

W. KEVIN BARRY

Prevention of Infant Deaths

SIR—In their interesting and well-informed comments on my paper on the above subject, Dr I. Rose (Dec. 28, 1946, p. 1006) and Drs I. M. Harkness and J. B. Cochrane (Jan. 18 p. 114) stressed the same point, namely, that the deaths of at least five infants cited might have been avoided by retaining them in hospital for a longer period. They are of course absolutely right in this, but it is also true to say as I tried to indicate, that it was because of the inadequate care they received on discharge due to the prevailing sociological conditions and at a time when they were unable to withstand such adverse conditions, that they did not survive. It is agreed that this was a consequence of their too early discharge, but this train of events would not necessarily apply where a premature baby goes to a good home with a capable and sensible mother. Drs Harkness and Cochrane in the second paragraph of their letter describe better than I could have done the sociological dangers to which many babies are exposed on leaving hospital, and a wider realization of this is needed. Nevertheless, the viewpoint of the hospital doctor must be appreciated for, quite apart from the shortage of beds and cots, the risk of cross infection cannot be excluded, and, other things being equal, the sooner a baby is out of hospital the better. The dangers of a poor home environment will often outweigh the potential dangers of cross-infection, but this will not always be so, in any case the hospital doctor must be kept informed of the sociological background of his cases, for without this knowledge he cannot decide whether a baby should be retained in hospital beyond the normal period. It was there that our arrangements were found to be wanting, and it was to remedy this that our scheme was devised.

I am glad to have the support of Drs Harkness and Cochrane for my claim for the provision of hostels where prematures and other debilitated babies can be hardened off before returning to unsatisfactory households, it is however probable that such hostels might have a greater part to play than that of mere postnatal sanctuaries but this is too large a question to enter into here. I regret I cannot give Dr Rose details of the discharge weight of the babies concerned but unfortunately I have not here available the records to consult. As regards blood counts, it was the practice when these cases were under treatment to do a routine blood count on every expectant mother where there was a suspicion of clinical anaemia or debility, and the blood counts quoted referred to the antenatal

14. Iron and vitamin preparations were available and were given almost as a routine, and liver preparations could also be used if and when required—I am, etc.,

J TUDOR LEWIS

Shortage of Nurses

SIR—Gloucester is to be congratulated on having evolved a practical scheme for the employment of part time nurses which will go a long way towards meeting the present hospital staff crisis. It is unfortunate that a number of authorities such as the Kent County Council have not yet launched a publicity campaign for the recruitment of these part-time workers and indeed are turning away from their hospitals both trained and untrained personnel who have volunteered for part-time work in response to the Government appeal.

It is also unfortunate that owing to an oversight an anomaly arose when the London County Council part-time scheme was first operated whereby nurses doing 30 hours in the week received more pay than those doing 40 hours. I understand that this anomaly will now be removed. Its removal will however accentuate the obvious disparity referred to by Miss Katharine F. Armstrong (March 15, p. 345) between the pay of the part time and the full time nurse. The argument in regard to nurses' emoluments cannot hold good indefinitely, since it is recognized by all those anxious to promote an adequate flow of suitable recruits to the profession that nurses should wherever possible, live out and in fact in many cases already do so.

The suggestion put forward by Dr L. Ley for preliminary training (March 15, p. 355) is excellent, and it is of course essential to the success of any long term scheme that nurses' training colleges should be integrated with the higher educational system of the country. It is, however, also essential that the rates of pay for student nurses should be drastically revised, not in the light of whether we can afford 6d a week more but in the light of whether we will be able to run our hospitals without a steady inflow of keen intelligent girls into the nursing profession—I am, etc.,

St Mary Cray Kent

BRIAN H. KIRMAN

SIR—Your correspondent Dr Leonard Ley (March 15, p. 355) has outlined in his letter some useful and wise suggestions whereby the recruiting of nurses can be accelerated. Would it be forgiven if I ventured to say that on a most important matter he has, in common with many medical men missed the point?

A woman who is in training, or who has trained, in the care of the sick is a "nurse" simply and solely and should be treated as such. In many hospitals nurses are messengers and it is quite a part of their routine to leave off any nursing duty which happens to be on hand just to run to such-and-such a ward, "fetch this," or "borrow that." It is not exaggeration to say that many a young nurse associates the advent of the doctor into the ward with being sent off to find forgotten X-ray films, notes, or to borrow, in a hurry some instrument in which the ward is lacking. The natural pride and interest that a young beginner to nursing feels in her work is rather rudely shaken when she downs tools to become a harassed messenger girl.

Is it too much to hope that soon we may see wards equipped each with such articles as Ryle's tubes ear syringes, steam kettles etc.? In how many wards are such articles as kidney dishes, enamel bowls, and trays at a premium? Why is so much time spent in sending off for such articles to be borrowed? As for the messages which must be fetched and delivered in all wards, cannot official runners be employed or, failing that, the under-training-age recruits? Surely it should be a thing unheard of for any nurse, however junior, to leave the ward work for any pretext whatsoever—except perhaps, the classical 'fire or haemorrhage'. In these matters doctors can help—I am etc.,

London E 17

CARMEN MORFEE

SIR—I wonder whether Dr Ley (March 15, p. 355) is aware that the General Nursing Council divided the Preliminary State Examination in 1938 in order that the subjects of anatomy, physiology and hygiene could be included in the general school

curriculum so that intending candidates might cover these subjects before entry to hospital for training. Pre nursing courses have already been established in 265 schools and technical colleges in England and Wales. The list can be obtained from the offices of the General Nursing Council. A girl completing a course can take Part I of the Preliminary Examination before entry to hospital. Last year over 12,000 candidates presented themselves for Part I of the Preliminary State Examination but unfortunately only quite a small number entered by way of a pre-nursing course.

The recruitment of sufficient nurses is an educational problem which can be solved only when the education authorities of the country take the responsibility which is theirs and when every school and technical college in the country has a pre nursing course. This measure would simplify recruitment, further it would lead to revision of the nursing curriculum in order that the knowledge of the basic sciences already gained might be used to form the best foundation for nursing training—I am, etc.

London NW 11

EVLYAN C. PERCI

Mengo Hospital Jubilee

SIR—May I draw the attention of readers of the *Journal* to a rather unusual medical anniversary. In February, 1897, after an adventurous three months' journey on foot for 800 miles from the coast there arrived at the capital of Uganda a party of missionaries, who included among their number the young Dr A. R. Cook and his future wife a nursing sister named Miss Catherine Timpson. Shortly before another pioneer Bishop Hannington while on the same journey, was murdered as he crossed the Uganda frontier.

In May, 1897 the first hospital to be established anywhere in this part of Africa was built of reeds and mud, and from that date without cessation a stream of patients has passed through the wards of this hospital—the figures for last year 1946 being 4,317. Out-patients numbered over 14,000, and nearly 900 operations were performed. There is to day a nurses and midwives training school with 110 students and each year some of these girls, qualified at a Government examination, pass out into numerous hospitals and maternity homes throughout East Africa, both Government and mission.

Space forbids mention of much of the fascinating history of this medical work, started by Sir Albert Cook, C.M.G. O.B.E. M.D., etc. and his brother J. H. Cook, M.S., F.R.C.S. but it is worth recording that the first vaccinations against smallpox in East Africa were performed here and the first case of sleeping sickness in Uganda recognized in these wards, apart from many other pieces of original work in therapeutics, public health and medical education. Fifty years in the life of a young African territory is a long time, and such a Jubilee should not pass unnoted in medical circles. With this in view the Uganda Branch of the British Medical Association is organizing an East African inter territorial meeting to celebrate the occasion during the first week in September. The work done in these years has been of the highest quality, as is exemplified by the orderly rows of bound case sheets in the hospital library dating back to the first case seen *en route* even before arrival. It is interesting to mention that on another shelf are bound copies of the *British Medical Journal* going back to the very early days of the century.

A programme of rebuilding urgently needed, is being undertaken to mark the occasion of the Jubilee at a cost of £30,000. If any readers should feel inclined to help with the carrying on of this valuable service for one of our African dependencies donations would be gratefully acknowledged by the Secretary of the Jubilee Appeal Box 161 Kampala, Uganda—I am, etc.

R. T. S. GOODCHILD
Medical Superintendent

Medical Certification

SIR—I was interested to read (March 15 p. 353) of Dr. Leslie Ballon's struggles with the Board of Trade to procure a "thermos" flask for one of his patients. I am recording a case of my own, as I think you will find it rather amusing though I am afraid I did not think it very amusing at the time—particularly as just then I was spending a large part of most days digging my car out of snow drifts.

Mrs. S. gave birth to a 5-lb (2.2 kg) child, and it was considered necessary to give the child three hourly feeds. As

ORAL VITAMIN D

in Lupus Vulgaris

Lupus vulgaris though uncommon is of such chronic nature that there always exists a pool of affected patients who constitute a serious social problem

Recent success in the treatment of lupus by massive oral dosage of vitamin D is therefore of great significance Backed by local therapy administration of High Potency Ostelin Tablets (calciferol) has evoked rapid

response in many cases A high proportion of cures has been reported even amongst cases of many years standing

Normal dosage is 150 000 iu daily, supplied by three High Potency Ostelin Tablets The usual dose is well received by most patients and toxic symptoms when they occur are generally mild treatment, of course should be adequately supervised

Tablets (50 000 iu) 25's and 100's
Dispersing size 1000

GLAXO LABORATORIES LTD GREENFORD MIDDLESEX BYRON 343

A treatment of TENO-SYNOVITIS by means of Elastoplast

Case History—On the 16th January a bricklayer, aged 31, complained of pain at the back of the wrist It was particularly noticeable when grasping

A radiograph revealed nothing abnormal, but clinically there was synovial crepitation in the extensors

Treatment — Fingers immobilised by postero-anterior strips of Elastoplast binding them over a roller bandage Another turn of Elastoplast bandage strapped the wrist

On the 23rd January there was still slight pain and Elastoplast was re-applied to the hand and wrist only

By the 30th Jan there were no symptoms The patient returned to work after 14 days, but the Elastoplast wrist strapping was retained for a further week

The details and illustration above are of an actual case T J Smith & Nephew, Ltd, manufacturers of Elastoplast, are privileged to publish this instance, typical of many in which their products have been used with success, in the belief that such authentic records will be of general interest

In Elastoplast elastic adhesive bandages a combination of the particular adhesive spread with the remarkable **STRETCH** and **REGAIN** properties, together provide the correct degree of compression and grip They mould readily to any part of the body without slipping, rubbing, or constriction Elastoplast bandages are available in widths of 2 in., 2½ in., 3 in., and 4 in. × 5/6 yds long when stretched Also 2 in wide × 1½ yds (stretched) Elastoplast, Elastocrepe, Jeloner and Gypsona are products of T J Smith & Nephew, Ltd, Hull

PAIN IS INTENSELY PERSONAL

Sympathetic understanding may assuage mental anguish but surcease from physical distress can come only from the relief of symptomatic pain

Veganin is particularly well adapted for the relief of menstrual distress since it is a synergistic association of codeine acetate, salicylic acid and phenacetin producing rapid and prolonged relief without ill effects

When it is necessary to relieve pain without incapacitating the patient try Veganin

RESTRICTED SUPPLIES
Owing to the shortage of certain supplies and the consequent limitation of output, chemists have been asked to give priority to doctors' prescriptions. Veganin is not advertised to the public.

HALVING EXPOSURE TIME with Ensign CRESTA X-RAY FILM

Wherever difficult technique is employed, and where busy X-ray departments need consistent routine radiographs Ensign CRESTA X-ray film is appreciated. Although so fast, this film gives fine definition, contrast and clarity. The reduction of exposure time is especially helpful in the radiography of children and in avoiding fatigue with cases of pregnancy.

nylon knot

she was unable to breast-feed the child, it was put on an artificial food. She asked me if I could give her a certificate for a thermos flask so that she could keep water hot for the night feeds. Accordingly I wrote out a medical certificate.

1st certificate—Please supply Mrs S with a "thermos" flask.

Reply—Certificate inadequate. State for what reason flask required.

2nd certificate—Please supply Mrs S with "thermos" flask, she is a nursing mother.

Reply—Inadequate. State why nursing mother should require thermos' flask.

3rd certificate—Please supply Mrs S with thermos' flask, she is a nursing mother and requires the flask to give the child night feeds.

Reply—Please state that Mrs S has no other means of cooking.

4th certificate—Please supply Mrs S with thermos' flask, she is a nursing mother and requires the flask to give the child night feeds. She has no other means of cooking.

By now the whole affair had become fantastic and I asked Mrs S if she really wanted me to go ahead with it. "Oh, no," she replied. "I have a friend who is an agricultural worker and he got a flask for me on a certificate from his boss"—I am, etc.

Remuneration under the Act

SIR—I have just read with great interest the letter of my namesake Dr R J Healey (March 15 p 352). I could not disagree more strongly with the suggestion made. During the war I had considerable experience of A.F. 1667 from the Army side and have since had some from the civilian. The trouble to obtain payment is so great and the remuneration so small that for months now I have forsworn anything to do with the remuneration.

To me it seems that payment by the numbers on a doctor's list is fair and reasonable, the doctor having simply to remember, when he gets a troublesome call, the numbers of those patients for whom during any year he is not called upon to do anything whatsoever. Such a condition is of course innate in any insurance system—I am, etc.

C W HEALEY

Basic Salary

SIR—Out of all the confusion of thought surrounding the National Health Service Act the crucial point has been clearly indicated by Dr D Saklatvala in his admirable letter (March 8 p 308)—viz. no basic salary. The basic salary is not in the patients' interests, and on that account alone should be resisted by all general practitioners. Let us all unite on this essential point and everything else will fall into its proper place.

The General Practitioners Subcommittee will have failed completely if they do not show the Minister that a basic salary will not be tolerated. We must have an adequate capitation fee remembering that this time it will not be subsidized by private practice. We must have access to the courts when necessary. There is no need for "direction" that can easily be overcome by an added sum per capita for those working in depressed or unpopular areas. Our practices can still remain our own under the capitation system. Limitation of lists will find work for all the new-comers. For our patients' sake the family should be the unit until the individuals leave home—I am, etc.

J A JAMIESON

Caloric Value of Toasted Bread

SIR—The statement that the caloric value of bread increases by 10% or 20% by toasting (*Journal* Feb 22) should go a long way towards solving the present world food shortage. It would for example only require the compulsory toasting of all bread in this country to effect a saving greater than that resulting from rationing it.

Perhaps however you did not mean to imply an absolute increase in calories by toasting but an apparent increase when expressed on the basis of dry weight of bread or toast. The drying of the bread during toasting naturally results in more calories per ounce (20 g.). But one normally does not eat one's bread in ounces but in slices and a slice of bread before or after toasting has of course the same caloric value. One might equally well refer to the decrease in caloric value of milk

when taken in tea, milk has a caloric value of about 20 per ounce, while milk in tea would have a caloric value of perhaps 3 per ounce. The caloric value of the milk has no more been reduced in this instance than that of bread is increased by toasting, the same number of calories are there but in a more or a less dispersed form—I am, etc.,

JOHN YUDKIN

Dirty Milk Bottles

SIR—During a recent visit to a large wholesale dairy in London by a number of doctors studying for the Diploma in Public Health, attention was drawn to the difficulty arising out of failure of the consumer to rinse out milk bottles after use. The one-third-of-a-pint bottles from schools comprise the dirtiest specimens. They are not only unrinsed but many contain broken straws and aluminium caps, while some are not completely emptied and contain curdled milk. Not only are these bottles hard to clean but in warm weather flies gain entry and breed on the sour milk.

It is surprising that milk bottles returned empty from schools should be received in this very dirty condition especially as the organizing bodies are public authorities. It would appear moreover, that a very valuable opportunity of instilling practical habits and knowledge of hygiene in children is missed. It should not be a matter of great difficulty or expense to organize a system by which children cleaned their own milk bottles and received some instruction on the reasons for so doing—I am, etc.

J H WILDMAN

"Trade Secrets"

SIR—Would it be of interest and benefit to open a discussion on "trade secrets" in your columns? I write in respect of surgery, though the subject applies also to the art of physical diagnosis in general as well as to technique in operations. It is fundamental that the ideal method of learning to operate is by serving an adequate apprenticeship. Thereafter skill and wisdom are the fruits of experience.

Most trade secrets are still passed by word of mouth both in the east and the west. How many of us consciously know that the secret of entering a subcutaneous vein depends upon three factors—viz. getting everything 'teed up' in a most unhurried fashion, experimenting until a proper oblique light falls upon the skin which has been rendered semi-transparent with methyl alcohol and 'catheterizing' the vein by inserting the needle exactly in the vein's axis while the left thumb of the operator makes traction on the vein distal to the site of the needle's entry? Is it realized that footwork is as essential to the tying of a surgeon's knot as it is to the skilled boxer? Watch an adept making his passes during either game.

I was invited to watch Mr Hamilton Stewart, of Bradford, using his trans-urethral tools. He works standing. His operating table is elevated almost to eye level. Since then I have done knee-cartilage and piles operations while standing at my work. The hands work better when footwork is permitted. Where in orthopaedic literature are we advised to apply a full-length compression dressing before releasing the tourniquet at a knee operation?—I am, etc.

Calgary, Canada

J A M CAMERON

The latest annual report on medical services in Nigeria (population 174,000) states that the general health of Europeans is, on the whole, good. Malaria is the commonest condition necessitating admission to hospital and accounts for about one-quarter of all in-patients. Diseases of the skin, enteritis, and diseases of the digestive system are, after malaria, most frequently encountered. Among the Africans most hospital admissions are for diseases of the skin, cellular tissues, and organs of locomotion. Pulmonary tuberculosis is still the commonest cause of invalidism among African officials and in 1945 was responsible for 18.9% of all invalidity. Venereal diseases account for a larger amount of hospitalization than malaria. In 1945 the number of in-patients with malaria was 8,569 but those with venereal disease numbered 11,372. In the south country there is a falling off in the number of cases of gonorrhoea treated, possibly due to the increasing activity of private practitioners and to self-medication with sulphonamides. In the north venereal disease remains as serious a problem as before. In 1945 Nigeria had for the first time on record an epidemic of louse-borne typhus (126 cases with a mortality rate of 25%). Prompt measures and the use of DDT controlled the epidemic.

Obituary

S MORTON MACKENZIE, M.B. B.Ch.

His old colleagues in the Council of the British Medical Association and in the Surrey Branch will learn with regret of the death on March 13 of Dr Morton Mackenzie of Dorking. For many years Dr Mackenzie was a very active figure in both the central and local affairs of the Association. He was a member of the Representative Body for fifteen years, a member of the Council for thirteen, and for the long period of eleven years (1922 to 1932) he presided over the Organization Committee. Here he found a sphere of activity in which he took particular delight. Nothing pleased him more than to report the constantly increasing membership of the Association, to encourage local honorary secretaries, and to spur the Divisions and Branches on to new activities. He was himself the embodiment of cheerfulness and energy. He served also for ten years on the Journal Committee and for five years on the Parliamentary Elections Committee. Anything which had to do with propaganda on behalf of the Association, with the recruitment of young practitioners to its ranks and with the enhancement of its reputation had his vigorous and enterprising support.

To the regret of all who had the opportunity of learning the value of his work—work of a kind which has not a wide appeal—Mackenzie withdrew from active participation in central affairs at about the time of the Association Centenary though he was then not much more than fifty years of age.

Stephen Morton Mackenzie, son of Sir Stephen Mackenzie, physician to the London Hospital and nephew of Sir Morell Mackenzie, the laryngologist, took his university course at Cambridge, and went to the London Hospital for his clinical training, qualifying M.R.C.S., L.R.C.P. in 1904, and M.B. B.Ch. in the following year. He settled down to a partnership practice in Dorking and became surgeon to the Dorking and District Hospital. He was also chairman of the Surrey Voluntary Hospitals Consultative Committee, and for fourteen years a member of the Surrey Panel Committee. He had been president of the Surrey Branch of the B.M.A. and remained vice-president. He was on the council of Epsom College and treasurer of the Surrey Medical Benevolent Society. In the war of 1914–18 he served as a temporary captain R.A.M.C. No practitioner was better known in his area and he was greatly esteemed by colleagues and patients alike.

FERGUS L. HENDERSON, M.B.

The death on Feb. 28 at the age of 54 of Dr Fergus Leslie Henderson has ended a life expended to the full in professional and public work in Glasgow.

A son of the manse, Dr Henderson was educated at Glasgow Academy and, after a distinguished scholastic career at Glasgow University, where he graduated in 1914. After a short period in general practice and in the city hospitals, his interest in radiology was stimulated by the late Dr James Riddell, one of Glasgow's pioneers in the use of x-rays. In the early days the interpretation of x-ray films was still largely an unexplored field but in conjunction with Sir Alexander MacGregor and the late Dr John Wilson, Dr Henderson correlated the appearances which he saw in the film with the findings of the clinician and helped to establish the place of the radiograph in the elucidation of the many diagnostic problems of chest work.

When the Corporation of Glasgow opened up its first radiological diagnostic station at Ruchill Dr Henderson was the natural choice as consultant and as the tuberculosis service expanded he became the final arbiter on practically all the chest radiography carried out by the public health department. In 1923, when the McAlpin Home introduced radiological equipment, he became consultant there. By many he will always be remembered for the efficiency of his work with the public health department, but his association with the McAlpin Home brought him into intimate contact with a wider circle of medical colleagues who as the years passed came to value his opinion more and more. Some years ago his service to the McAlpin Home was recognized by his appointment to the board of management, and here his wisdom and administrative

ability found another outlet. Among his other appointments was that of radiological consultant in the West of Scotland to the Ministry of Pensions. For many years he was also in charge of radiotherapy in the Cancer Hospital.

Two other interests were important in his life. A man of sincere religious beliefs, he formed an association with Ruchill Church in 1914 when he became an officer in the 69th Company of the Boys Brigade. Two years later he took charge of the company, and during the last thirty years he had built it up to become one of the largest and most effective in Glasgow. A pioneer in his realization of the need for proper recreational opportunities among working class boys, he set in train schemes which culminated in the purchase of an athletic ground at Maryhill which might have been the envy of any wealthy public school. Here the boys enjoyed first-class playing facilities and learned the qualities of real sportsmanship under the guidance of a man to whom playing the game in every aspect of living was as natural as breathing.

His other enthusiasm was music. A life-long supporter of the Scottish Orchestra he had been a valued member of the committee of management for many years. Before 1939 his interest in music was fused with his Boys Brigade activities and the annual production of a Gilbert and Sullivan opera was one of the features of his company's activities.

His private circle of close friends was small, for his natural modesty and shyness formed a mantle which kept him somewhat aloof. But a wide circle respected him as a man of real integrity whose sense of responsibility was great and whose opinion was always fearless and forthright. He was one of the world's givers, and his passing is felt the more keenly because there are so few to fill his place. In his work at Ruchill it would have been easy for him to seek the limelight which such a unique piece of public service deserved, but that was not his way. His enduring record is there, however, in the playing fields of the Ruchill Church and in the imprint he has left on the minds and in the lives of a multitude of the young citizens of Glasgow. Dr Henderson was unmarried. He is survived by his mother, two brothers and a sister.

WILLIAM DUIGAN, M.B.

Oxford lost one of its oldest and most respected practitioners when William Duigan died on Feb. 24. Dr Duigan was born in 1865 the son of Dr J. Duigan of Gainsborough, Lincolnshire, and was educated at Loretto, Christ's College, Cambridge, and the London Hospital. An M.A. at Cambridge in 1886 was followed by the M.B., Ch.B. in 1890 and shortly afterwards he began his career as a general practitioner at Woodstock. In the 1914–18 war he was a captain R.A.M.C.(T) attached to the 3rd Southern General Hospital at Oxford where he became more and more interested in the administration of anaesthetics. After the war he was appointed honorary anaesthetist to the Radcliffe Infirmary later becoming its director of anaesthetics and chief anaesthetist. There he built up a reputation as a safe and helpful assistant and his services as an anaesthetist were in constant demand by the surgeons of his day both in hospital and in private practice. Later, with the institution of the Nuffield professorship, Dr Duigan's active connexion with the department gradually ceased. Till then successive generations of medical students had reason to remember with gratitude his painstaking and skilled tuition.

Dr Duigan suffered from fibrosis, and as he grew older this became a crippling ailment while in 1929 and 1931 he had to undergo two operations for chronic glaucoma which left his sight impaired. Nevertheless, for several years afterwards he continued in active work as a general practitioner with a substantial list of lifelong patients who had no thought of going elsewhere. As the age of 80 approached, however, he had reluctantly to give up work altogether. Dr Duigan was a great traveller and he delighted in touring with his car and family through this or that country abroad. Other relaxations he found in fencing, fishing and gardening, and especially in the culture of roses.

Dr Duigan gave many years of devoted service to the British Medical Association and to the local medical profession. He was hon. sec. of the Oxford Medical Society from 1897 to 1906. A member of the B.M.A. since 1891 he was hon. sec. of the Oxford Division and of the Reading, Oxford, and Maidenhead Branch 1902 to 1913, local secretary for the

Annual Meeting at Oxford in 1904 representative at the Annual Representative Meetings 1905-7 and president of the Oxford and Reading Branch in 1922-3. He was also a member of the Oxford Medical Literary Club for forty-five years, and the University of Oxford honoured him with the grant of its MA while University College, Oxford made him a member of its Fellows' Common Room. Dr Dugan married in 1902 Jane the youngest daughter of the late General Sir Horace Anderson KCB. She died in 1930. They had one daughter who survives her father and to whom as his constant and devoted companion in later years the local medical profession has extended its sympathy and gratitude.

Dr G. A. Auden formerly professor of public health in the University of Birmingham, writes. In the obituary notice of Dr T. W. Shore in the *Journal* of March 8 (p. 315) mention is made of the open scholarship in science at St Bartholomew's Hospital won by him in 1880. The late Sir Arthur Shipley FRS, tutor, and later master, of Christ's College, Cambridge and Vice-Chancellor of the University, sometimes used to say with a twinkle in his eye that he owed all his success at Cambridge to the fact that he had been beaten in that scholarship by Tommy Shore otherwise he would have been a hard worked country practitioner. For, after his defeat at Barts he obtained an open science scholarship at Christ's College, where he spent the rest of his days with such manifest enjoyment of life and where he gained the affection of everyone who was privileged to know him. Truly Heaven from all creatures hides the book of fate.

Dr W. Norwood East writes. May I add a few words to your sympathetic reference (March 15, p. 357) to the premature death of Dr W. H. DE B. HUBERT? Those of us who were associated with him at Wormwood Scrubs Prison in the years before the war will particularly remember him for his conspicuous ability, charming personality, loyalty and wide vision as well as for the remarkable ease with which he gained the confidence and co-operation of a difficult group of patients. From the commencement of his work at the prison it was clear that his practical approach to mental analysis and his diagnostic acumen would prevent him from committing the mistakes which are liable to occur at first when dealing with law-breakers. His ready response, clear penetration, good humour and constructive criticism, together with a readiness for his own work to be criticized, made him an easy collaborator. We are entitled to believe that had it not been for the exigencies of war Hubert would have made further contributions to the psychiatric approach to crime and criminals.

Dr GEORGE WISHART MCINTOSH died suddenly at his home in Kirkcaldy on Feb. 27. He studied medicine at Edinburgh University where he graduated MB, CM in 1896. In 1902 he took the B.Sc. (Public Health) and after a visit to America and some preliminary assistantships he began general practice in Kirkcaldy. This continued until 1910 when he was appointed medical officer of health for Kirkcaldy and Dysart. He occupied this post for twenty-seven years and during his tenure of office was responsible for the modernization of all his health services. His previous experience of general practice gave him a broad outlook on medical problems and local practitioners found in him a sympathetic and understanding colleague. They showed their appreciation by entertaining him to a dinner and making a formal presentation on the occasion of his retirement in 1937. During the recent war he emerged from his retirement and did valuable service by assisting the five medical officers of health in organizing the ARP services for the county. Dr McIntosh had been a member of the British Medical Association since 1898 and in 1932-3 was president of the Fifeshire Branch. For many years he was a member of the Branch Council where his shrewd common sense was always helpful. He was a member of the Caledonian Medical Society and a Fellow of the Society of Medical Officers of Health. Dr McIntosh was for many years a keen Territorial and served in the 7th Black Watch (RHR). During the first world war he commanded a company in this famous regiment which he took to France. After some active service abroad he was invalided home and was there transferred to the RAMC with the rank of major. After the war he was awarded the TD. Apart from his profession he had many other interests. He was a staunch member of the Baptist Church and an original member of the Rotary Club. In fact he had just returned home from the club's weekly luncheon when his sudden death occurred. He was also a justice of the peace for Fife. Always fond of sport he played golf in his earlier days and was a keen curler. Latterly he had

devoted himself to bowling and at the time of his death was president of the Victoria Bowling Club. Dr McIntosh had a fine personality. His uprightness of character, his kindness and generosity and above all his geniality and great gift of humour made him a general favourite.

WALTER GRAHAME STEWART died on March 6 after being in poor health for some months. He was born in Port Elizabeth, South Africa, in 1874 and educated at Dulwich College and Guy's Hospital, qualifying in 1899 and taking the London MB in the same year. After being house-physician at Guy's and clinical assistant at the Royal London Ophthalmic Hospital and at the Throat Hospital Golden Square, he settled in Ware, Hertfordshire, in 1901. He took over a busy general practice being district medical officer and public vaccinator and medical officer to the Post Office and to the Herts Training School, Chapmore End. He was honorary medical officer to the Hertford County Hospital from 1906 till 1916 and medical superintendent of the East Herts Joint Hospital for 33 years until his retirement in 1945. He was later elected a member of the board an office he held until his death. During the 1914-18 war Dr Stewart was commandant of the Ware VAD Hospital of which his wife was lady superintendent and matron. He was appointed MBE in 1920 for his war services. Later he served on the Hertford Pensions Board. Divisional surgeon to the Ware Division of the St John Ambulance Brigade since 1929, he undertook the training and organization of the town first-aid service during the recent war and was medical officer to the first-aid post. Among his writings was an article in the *Journal* on enteric fever. Dr Stewart took an active part in the public affairs of Ware. A keen churchman he was for many years a churchwarden at Ware Parish Church. He was elected to the urban district council in 1923, and was chairman from 1928-30 and from 1939-44. He remained a member of the council up to the time of his death. He was a member of the British Medical Association for thirty-two years, chairman of the East Herts Division in 1930 and again in 1935 and president of the Hertfordshire Branch from 1936-8. He married in 1902 Rebecca Charlotte daughter of the late Major-General F. F. Daniell, his wife died in 1933 and he leaves one son, Lieut. Col. Gordon W. F. Stewart, R.A., and two daughters.

Dr GEORGE MONTGOMERY DRURY of Cheadle Heath, Cheshire, died at the age of 79 on Feb. 21. A student of the Royal College of Surgeons, Edinburgh, and Queen's College, Cork, he qualified in 1893 and had been in general practice all his life. Dr Drury had one of the oldest practices in Cheadle Heath and had been well known there for over fifty years. He had long been associated with St Augustine's Church, Cheadle Heath and he had been a member of the British Medical Association since 1898.

Dr WILLIAM GLOAG GALLETT, of Anerley, died at the age of 84 on Feb. 23. He qualified MB, CM at Edinburgh in 1884 and was in practice in Sunderland for a few years. He then moved to Northwold, Norfolk, and continued in general practice there from 1893 until 1915 when he joined the RAMC. In 1918 he was appointed to the staff of the Ministry of Pensions and he continued his work on medical boards until failing eyesight necessitated his retirement in 1928. Dr Gallett was a man of studious disposition and a quiet and lovable character.

Dr JOHN ALEXANDER NEILAN died at the age of 70 on March 16 at Scarborough. He was in practice at Seaham for forty-eight years. Dr Neilan, who qualified in Dublin, went from Ireland to Seaham in 1899 as a partner of the late Dr L. G. Dillon. Latterly he was in partnership with his brother Dr Charles James Neilan, and Dr H. J. Weir. He left Seaham last December and went into retirement at Cloughton, near Scarborough. For some years he was medical officer of health to Seaham Urban Council. During the war he was medical officer to Seaham Home Guard, holding the rank of major.

FREDERICK CHARLES PRIDHAM died at his home in Darlington on March 11. He had been ailing for some time but with the unquenchable courage and thought for others that characterized his whole mode of life he did his job as a doctor almost to the last. He was a student of St Thomas's Hospital, and a worthy son of that great foundation, of which he later became casualty house-surgeon. Later he was house surgeon to Chesterfield Infirmary, and eventually settled in Darlington in general practice in 1913 the year in which he took the FRCSEd. During the 1914-8 war he joined the RAMC and serving as a captain, was gassed while overseas. He was

an honorary senior surgeon of the Darlington Memorial Hospital for many years. He had been a member of the British Medical Association since 1910 and was chairman of the Darlington Division in 1927-8. He devoted his leisure hours to the medico-political side of his profession and was a tower of strength to the B.M.A. in all its activities. He was much beloved by his own patients and by others whom he had helped back to health in the hospital. In the minds of his colleagues he will always remain a model of what each of them would wish to be.

Dr JOSEPH ELLISON died on March 14 at Alwoodley Leeds aged 82. He was in practice in the Beeston district of Leeds for nearly fifty years, and retired about ten years ago. A native of Leeds Dr Ellison was a student at the Leeds School of Medicine at the same time as the late Lord Moynihan.

Medico-Legal

RESPONSIBILITY FOR DRUGS SUPPLIED

A recent decision of the High Court¹ opens up a serious new legal threat to medical practitioners, though it concerns a firm of veterinary surgeons. In the summer of 1945 a drug retailing firm recommended to the veterinary surgeons a new preparation known as corynebacterium toxoid for use against summer mastitis in dairy cattle. The managing director assured them that it was perfectly harmless. They inoculated with it two dairy herds, and sixty cows suffered from serious illness. The dairy farmers sued the veterinary surgeons, who joined as co-defendants the suppliers of the toxoid, who in their turn joined the manufacturers.

The judge, Mr Justice Hallett, said that if the veterinary surgeons had recommended the toxoid, supplied it, charged the farmers for it and left the farmers to administer it, they would undoubtedly have been liable. If they had rendered a bill charging for the toxoid as one item and for their services as another, they would also have been liable. He could not see how their liability was lessened by the mere fact that they themselves injected the toxoid. He therefore concluded that there was an implied condition in the contract between the two parties that the substance to be used for the inoculation should be reasonably fit for the purpose of inoculating the cattle against summer mastitis. The condition had not been fulfilled and the farmers could recover damages against the veterinary surgeons; the veterinary surgeons could recover from the suppliers, and the suppliers again from the manufacturers. He assessed the damages at £3,341 18s 6d with costs.

This decision makes new law of a very disturbing kind. If it remains unchallenged, a doctor may be called upon to pay heavy damages if any drug, injection, or appliance which he uses should cause harm through not being reasonably fit for the purpose for which it is intended. A writer in the *Law Journal* suggests a cumbersome form of disclaimer of warranty which might afford partial protection but is a general practitioner to produce this every time he dispenses a bottle of medicine? To shoulder the consequences of our own mistakes is bad enough, to be responsible for those of drug manufacturers would be crushing. In view of the possibility of an appeal, further comment must be withheld.

2 1946 96 681

The World Federation of Scientific Workers has appointed Mr J. G. Crowther Secretary General Designate (London Office, 15 Half Moon Street W1). The President of the Federation is Prof. F. Joliot Curie, the High Commissioner for Atomic Energy in France. The Federation was founded last year at a conference convened by the British Association of Scientific Workers and attended by associations of scientists from five continents. The World Federation serves as a centre through which the various national associations render each other mutual advice and encouragement. It helps the growth of the individual associations in their own countries and assists them to work out common aims and methods of organization. It is preparing a charter of the rights and duties of scientists to serve as a guide model to scientists in all countries.

Medical Notes in Parliament

SCOTTISH HEALTH SERVICE BILL

The remaining Clauses of the National Health Service (Scotland) Bill were approved by the Standing Committee on Scottish Bills on March 18.

Transfer and Compensation

On Clause 65 Mr J. S. C. REID moved to extend the payment of compensation to persons who immediately before the appointed day had devoted a substantial amount of their time to employment with voluntary hospitals, local authorities, insurance committees or such other bodies as might be prescribed. He said that under the Act as it stood there was provision for transfer or compensation of whole-time officers, but he could find none with regard to part-time officers. He held that if a man had been doing this work he should be taken over as he hoped the Minister would say that such men if they desired it would be given whole-time employment under the new scheme. A number, however, were unable to accept offers of that kind. Why should they not be compensated?

Mr THORNTON KEMSLEY said the Clause was another example of English legislation being copied blindly without cognizance of the special conditions in Scotland.

Mr BUCHANAN regretted that he could not accept the amendment. It was then rejected by 17 to 12. On the motion that the Clause stand part of the Bill, Mr REID asked whether it included employees of a contributory scheme who were not employed directly by hospitals.

Sir THOMAS MOORE asked whether when full-time servants were transferred to the executive councils they would enjoy superannuation rates based on their past services, or would come under an entirely new system.

Mr BUCHANAN replied that no man would be the worse off as the result of being taken over. His rights under the original scheme would be safeguarded. Those who were employed full-time by hospitals as collectors were also amply safeguarded. Full-time collectors employed in Scotland by associations for collecting for hospitals numbered only seven, and the Department had practically made arrangements for giving them full-time employment. He understood that in England a number of collecting associations were going to continue and would be given certain other matters to attend to, but they were not likely to continue in Scotland. Clauses 65 and 66 were then ordered to stand part of the Bill.

Mr BUCHANAN said Clause 67 gave the Secretary of State power to hold inquiries so that he would not be forced to make a decision without this procedure. This Clause was also ordered to stand part of the Bill as was Clause 68. Clause 70 was ordered to stand part on an assurance by Mr Buchanan that there would be no novelties of procedure in the making of regulations under the Bill. Clause 71 as amended was approved, and so were Clauses 72 to 76. Clause 77 was accepted after Mr Buchanan had said that the word "asylum" had got into a wrong setting and the people engaged in this work would like a different word. This did not mean that the law was different. He promised to insert during the Report Stage words which would make clear that the Ministry only intended in this Clause to cover the Act of 1857.

"Remunerative Time"

On Clause 78 Mr REID withdrew an amendment which he proposed to declare that "remunerative time" included any time during which a person would normally be occupied in remunerative work. He said a doctor would lose remunerative time from his practice or consulting room while attending boards set up under the Bill. Doctors ought to be compensated for loss of time.

Mr BUCHANAN replied that the Lindsay Committee had inquired into the whole question of lost time in public work and its report was being printed. The Government must have this report in front of it before any action could be taken. If the Government decided to take action on this report the Scottish office intended to operate it in the widest possible terms so as to provide for the loss of remuneration of all people concerned. The amendment was withdrawn.

Dr MORGAN inquired about the meaning of the word "hospital" and the phrase "persons requiring medical rehabilitation." He wished to make sure that the definition included a rehabilitation centre where there was no question of medical or surgical treatment but a man was prepared for restoration to his former work.

Mr BUCHANAN said the point was important. In Scotland a great experiment was carried on at Gleneagles where people were not so much medically treated as equipped for some useful service to themselves and to the community. The Government intended to take over that work as a part of medical treatment in the widest sense. Clause 79 was then ordered to stand part of the Bill.

Scottish Health Services Council

Discussion followed on the First Schedule. Mr McKIE said the Bill gave the Secretary of State wide powers on how the Scottish Health Services Council and the Advisory Committees were to be selected. Mr WATSON thought the medical profession was over-represented on the proposed bodies and that there should be better representation of local authorities. Sir THOMAS MOORE said doctors, dentists and midwives were more qualified to exercise responsibility than anybody else. One of the weaknesses of local authorities was that the medical profession had been largely ignored by them.

Resuming the debate on March 19, Sir THOMAS MOORE said he agreed with Mr Westwood in regard to professional practitioners who were to be members of the Scottish Health Services Council but his advisers had been lax in regard to other healers who were unorthodox. He referred to homoeopaths and osteopaths. The osteopath was supported in many cases by the orthodox practitioner, but at present neither homoeopaths nor osteopaths were represented on the Council.

Mr BUCHANAN said that in most things the Government had accepted certain standards. The Secretary of State had an open mind and did not think these people wrong because they were in competition with older ideas. Mr Westwood had no feelings on the possibility of the homoeopathic doctor being grafted into this system. It would be better if this development came by its own growth rather than by the Secretary of State forcing it. Concerning the general composition of the bodies with which the Schedule dealt there had been a feeling that doctors were over-represented as against local authorities. The Government took the view that in no case should the medical profession have a preponderance of the representation.

Mr CARMICHAEL said the composition of the Council disturbed many members. There were 18 medical practitioners on a Council of 35. Laymen were completely overwhelmed by the members who would represent the professions. Social health services had in the main been the result not of the work of the medical profession but of ordinary men and women taking a broad view of health. Nobody could argue that the medical profession pioneered the supply of milk and meals to schools. He asked Mr Westwood to see whether it was possible to have one member of the Council elected from the local authorities.

Need for Co-operation

Mr WESTWOOD said it was impossible to allow every interest to be represented. If some bodies were left out their interests would be taken into consideration. He could not agree to elect representatives direct from the public health authorities in Scotland which numbered about 55. After consultation with the medical authorities he had increased from four to five the number of representatives with local government experience. The medical representation of 18 was to be drawn from all sides of the profession from specialists as well as from medical practitioners. In addition the Government might have to draw upon medical officers of health. So far as he could see there could be no possible combination among the 18 medical representatives to give advice which would be detrimental to the Service. He would have consultations again with the medical profession. He could not make a success of the Service unless he had the whole-hearted co-operation of that profession but before the Report Stage he would see if it were possible to increase the numbers of those who would represent local authorities. The question of representation for the homoeopathic school of medicine would not be overlooked. He had not had consultations with the homoeopaths but had received representations. Homoeopathy was recognized but osteopathy was not. He was entitled therefore, to take homoeopaths into consultation and consideration.

Mr GALLACHER said it was far more important that the people whose health was at stake should be represented. Doctors and others associated with the medical profession could give their services but it was not necessary that they should be on the Council. Mr SCOLLAN was astonished that in the negotiations the medical profession had asked for a preponderance of 18 out of 35.

Mr WESTWOOD said there were no negotiations in the ordinary sense. There were discussions but the final decision was with the Selecting Committee and the House.

Mr MCKINLAY asked whether the allopaths would keep the homoeopaths from being taken into consultation. If it was within the power of the allopaths to keep the homoeopathic physicians outside, they would. Ten years ago Glasgow Corporation passed a resolution that homoeopaths were to get all facilities in Glasgow hospitals. It was left to the medical officer to make the necessary arrangements but there had never been a homoeopathic practitioner in the hospitals to dispense even the smallest pellet. In the medical office of a local authority he had found that the doctors had no ideas outside their own profession. He asked that there should be on the Council representatives of the medical profession with local government experience.

Technical Advice

Dr STEPHEN TAYLOR said that in the English Bill the medical profession had done rather better. It had got 21 members instead of 18. Medical committees in Scotland had done valuable work in the past. The purpose of the Council was to give technical advice. It would set up subcommittees for such subjects as maternity and child welfare, skin diseases, and special hospitals, but it certainly would not be running hospitals. If the Government wished to get good medical advice it needed experts to give it. Medicine now had so many branches that to get a sufficiency of experts a large medical representation was needed. He reminded the Committee that not all the medical profession was in favour of the Service which was being set up. Many doctors had doubts about it and felt that they were having to make big sacrifices. They had indicated that at any rate their advice should be heeded in the running of the Service. To regard the medical profession as incorrigible was the doctrine of despair. He hoped that after the Bill had been in operation for a few years the profession would bless the day when it had been passed.

Mr J. S. C. REID said that if the services to be set up under the Bill were regarded primarily as services to cure the patient the doctors were not over-represented on the Council. If as many Labour members appeared to think the Bill was designed primarily to set up a bureaucracy the form of which was more important than the curing of patients then the views of Government supporters were correct and the medical elements should be smaller.

Mr WESTWOOD said that running all through the Bill and through the Schedule there was provision for those with experience of local government. It might be that the medical profession would not object to an increase in the number of such persons to six or seven. The First Schedule was then approved by 22 to 11 and the Second Schedule, on hospital endowments, was approved with consequential amendments. The Third Schedule was also accepted.

Chairmen of Boards

On the Fourth Schedule Mr REID moved an amendment designed to leave to hospital boards the selection of their own chairmen.

Mr WESTWOOD said he had not the slightest desire that these regional boards should be run on rubber-stamp lines. They could be run on different lines in different regions, but the Secretary of State must see that the person appointed as chairman was a proper person with the highest qualifications. Mr REID's amendment was defeated by 22 to 12.

Mr WILLIAM ROSS moved to provide that at least one half of the members of each regional hospital board should be persons other than medical practitioners. He said that in the Schedule as it stood there was a grave danger that the regional boards and later the boards of management would be overloaded with medical practitioners. If the medical profession provided the largest number of representatives there was always the danger that the medical profession would be told that they were running these hospitals for the benefit of the doctors and not for the benefit of the patients. The Committee agreed to the amendment.

Mr WESTWOOD accepted an amendment moved by Mr REID authorizing boards of management to elect their own chairmen. On the motion that the Schedule as amended stand part of the Bill Mr CARMICHAEL asked about local government representation on regional hospital boards. He argued that this element should be in the majority.

Sir BASIL NEVEN-SPENCE asked why the Royal College of Surgeons and the Royal College of Physicians and also the colleges in Glasgow were not to have a say in the appointment of these committees.

Mr BUCHANAN said the Government would consult the local authorities to the fullest possible degree. It intended to give the colleges representation under Part II (c). The Government had not the vaguest idea what the size of the Board would be.

except that it must be of manageable size. The Fourth Schedule was then agreed to. The Fifth Schedule was also accepted after discussion.

Continuing on March 20 the examination of the Sixth Schedule Mr NIALL MACPHERSON said nothing would be more disastrous than for this great system to start on the assumption that the medical profession was antagonistic to the Secretary of State. It would be far better for the medical profession to appoint the medical, dental, and pharmaceutical representatives on the executive council, and for the local authorities to appoint their representatives, the Secretary of State appointing none at all.

Mr BUCHANAN replied to the plea of Sir Thomas Moore for the homoeopathic doctor. This type of doctor was fully qualified and was like any other specialist, but the Government had not picked members of the medical profession because they were specialists. It must be for the doctors themselves to choose what people they proposed to have. There were good reasons for the appointment of four members by the Secretary of State. The proposed body was as near as the Government could get to what used to be called the 'Borough Committee'.

Mr MCKINLAY asked what was the local medical committee which had the right to appoint seven members. Was it the medical committee of the British Medical Association?

Mr BUCHANAN said no, it was the medical committee recognized under the Bill. The Standing Committee then agreed to the Sixth Schedule.

Scottish Medical Practices Committee

On the Seventh Schedule Cmdr CLARK HUTCHISON moved to leave out paragraph 5 of the Schedule, which provides that proceedings of the committee shall not be invalidated by any vacancy in its membership or by any defect in the appointment for qualification of any member. He said his friends felt there ought to be no doubt of the qualifications and suitability of the members.

Mr BUCHANAN said that without this paragraph it would be impossible if one of the members died to carry on the work until another man was appointed. Without the latter part of the paragraph there would be the same difficulty if, after a member had been appointed, it was found that in some way he might not be a proper person to be a member. If he had taken part in the work of the committee everybody who had received a certificate from the committee would have to be re-certified.

The amendment was withdrawn and, on the question that the Schedule stand part, Cmdr HUTCHISON pointed out that nothing in it laid down what should be a quorum of the Medical Practices Committee to adjudicate upon cases at any one time. If some members of the committee had to travel long distances and were busy men they might be tempted not to attend and important decisions might be made by two or three instead of by the full committee. The committee had considerable powers to influence the careers of young doctors.

Mr BUCHANAN said the Government proposed to allow each of these committees to fix its own quorum. If a rigid quorum were laid down for a country district, hardship might be inflicted on a doctor because it might be a long time before the business was settled. Although there was a committee for the whole country this committee might have to go to many districts. He did not wish it to call doctors from Inverness and such places. Instead it might meet in Inverness. To get four or five people to go to Inverness might be difficult, and the committee should be trusted to fix its own quorum regulations, and standing orders.

Mr MACPHERSON said people whose cases came before the committee would far rather have a full hearing with the quorum.

Mr BUCHANAN said he would look into the matter again, but in his own mind he was against it. The Medical Practices Committee was being trusted with great powers yet it appeared the only thing its critics could not trust it with was its own quorum. If any applicant felt that he was not getting full representation he could apply for an adjournment. The Standing Committee then agreed to the Seventh Schedule.

On the Eighth Schedule Mr BUCHANAN moved an amendment to make the Lord President of the Court of Session the authority who should appoint the chairman of the tribunal. The Committee agreed to the amendment and to the Schedule.

Lunatics and Mental Defectives

On the Ninth Schedule Mr BUCHANAN said that in view of the passing of this Bill the lunacy laws must be brought up to date within the next two or three years, apart from any alterations made under this Schedule. In the Schedule the Government proposed two or three changes. One was that mental hospitals and institutions for mental defectives were in future

to be provided by the Secretary of State instead of by the local bodies. The Government was also ending the detention of lunatics in poorhouses. Private patients and the Poor Law lunatics or the Poor Law mental defectives were to have the same treatment. The whole matter was codified under the new National Health Service arrangement. All this made the Schedule long and complicated. Sir Basil Neven Spence deserved credit for the work which he had done on the reform of the lunacy laws in Scotland. The Government hoped to introduce a Bill dealing with this subject at an early date. Private asylums would be taken over provided they were not carried on for profit. The Committee agreed to the Ninth Schedule.

Cmdr HUTCHISON moved to leave out of the Tenth Schedule the paragraph dealing with expenses which put a limit of five guineas a day for the services of any officer engaged on an inquiry. This paragraph also provides that expenses incurred by the Secretary of State shall be paid by the parties.

Mr BUCHANAN could not accept this amendment. Further pressed, he indicated that he would reconsider the matter. The amendment was withdrawn, as was another by Cmdr HUTCHISON to substitute ten guineas for five guineas. Mr BUCHANAN said that if it was necessary to appoint a person at a higher fee the Secretary of State had the power. An amendment enjoining publication of a full report of the inquiry was also negatived. Mr BUCHANAN said that a decision on publication had always rested with the Secretary of State and it was essential to the working of the scheme that this should continue. The Tenth Schedule was approved.

On the Eleventh Schedule Mr BUCHANAN moved an amendment authorizing the giving of convalescent treatment to a person recovering from infectious disease. This amendment was accepted, the Schedule as amended was approved, and consideration of the Bill was concluded.

The Bill was ordered to be reported as amended to the House.

PENICILLIN BILL

LORD AMMON in the House of Lords on March 18 formally moved the Second Reading of the Penicillin Bill.

LORD LISTOWEL, for the Government, said its purpose was to control the sale and supply to the public of penicillin or any substance with similar properties. The Bill would prevent such drugs and preparations reaching the public unless supplied or sold by a doctor, a dentist or a veterinary surgeon, or by a chemist acting on a prescription drawn up by such a person. The production of penicillin had steadily increased and there was now enough for all medical purposes at home leaving some for export. There was no longer any justification for continuing to enforce Orders under the Defence Regulations which had been authorized by Parliament to conserve a limited supply of this drug. Before deciding whether penicillin should be sold freely and without restriction or should be subject to some new statutory control the Government consulted Sir Alexander Fleming, Prof R V Christie, Col L W Harrison and Sir Philip Panton. Their unanimous opinion was that unrestricted access to penicillin would do grave injury to the public health. The most serious danger would arise when a patient took too small a quantity. This caused germs to lose their sensitivity to penicillin. People who acquired this immunity to penicillin would not only harm themselves but would be a danger to their families. The temptation to self-treatment or to amateur treatment in venereal disease to avoid publicity would be almost irresistible if penicillin could be obtained at any retail shop or store. The results would be injurious to health. This again would add to the grave difficulty of preventing the spread of diseases. The indiscriminate use of penicillin might also lead to dermatitis and ulcers of the mouth. In no other way than by legislation could the use of penicillin be effectively controlled. There would be no interference with the wholesale trade in these drugs and preparations nor with the supply to doctors and surgeons, to hospitals and nursing homes, to bodies doing medical research, or to Government Departments. Clause 1 of the Bill set out the restrictions on the sale and supply of penicillin and other substances. It also provided exemption from restrictions where these drugs could change hands without prejudice to health. Subsection 3 of this Clause provided that the same prescription should not be used more than once nor after three months unless the person signing it directed otherwise. Clause 2 applied the Bill to penicillin and to such other substances prescribed in regulations made by the appropriate Minister after consultation with the Medical Research Council.

Lozenges and Snuff

LORD STRABOLGI said he had been in touch with Sir Alexander Fleming with regard to the terms of the Bill. Where penicillin

lozenges were prescribed, perhaps 100 at a time, and were used for some chronic complaint, the mouth and throat would become an ideal breeding ground for the resistant strain of streptococcus. Not more than two dozen tablets should be dispensed to any person without further authority from the practitioner. He asked whether the Bill could be amended to cover this point.

LORD AMULREE welcomed the Bill but said that certain firms making cosmetics sought to increase the sale of these goods by calling attention to the fact that they contained penicillin. The preparations contained such a minute quantity as to be completely valueless. This was calculated to bring penicillin into disrepute. He was not clear whether the remarks of Lord Strabolgi about penicillin lozenges would also apply to penicillin snuff. This was good for the after-effects of colds and catarrh, and he understood it was safe. It tended to lose its properties quickly. It seemed hard to make a patient go back to his doctor for a prescription for penicillin snuff each time he caught a cold when it could be made possible for him to get a repeat supply on the original prescription.

LORD LISTOWEL said the responsibility for not prescribing too large a quantity of penicillin at one time fell upon the medical profession rather than on the Government. Penicillin was the first of a series of new substances on which experiments were being made. The most advanced of the other preparations was streptomycin, on which the Medical Research Council was conducting tests. Too little was known about its properties for it to be specifically mentioned in the Bill.

The Bill was read a second time and referred to a Committee of the whole House.

University Grants

In reply to Sir Ernest Graham-Little on March 10 Mr DALTON announced receipt of a report from the University Grants Committee on the needs of the universities for the five years 1947-52. He proposed to resume the pre-war practice of settling Exchequer grants to the universities for periods of five years. They would need Exchequer grants on a rising scale for some time to effect improvements which were due even before the war and to increase the number of students. He proposed that Parliament should be asked to provide recurrent grants rising from £9,000,000 for the academic year 1947-8 to £9,970,000 for 1948-9 and thence by annual increments of £60,000 to £11,920,000 for 1951-2. The recurrent grants for the present academic year would amount to between £6,000,000 and £7,000,000. These figures excluded the grants of £500,000 now made to teaching hospitals which would continue during the financial year 1947-8 and the amount of which for future years had not yet been determined. The University Grants Committee estimated that the universities' requirements of development would necessitate during the quinquennium non-recurrent grants amounting to £50,000,000 of which £40,000,000 would be for new buildings and £10,000,000 for acquiring sites, existing buildings and new equipment. He accepted this estimate of the need and would do his best to meet it. Even after allowing for a high degree of priority the best forecast at present possible did not justify the expectation that universities would be able to undertake more than £20,000,000 worth of new building during the quinquennium. Such a restriction of the building programme must retard to some extent the expansion which the universities had in view. He proposed to review the position from year to year. The sum which Parliament would be asked to vote for the financial year 1947-8 was £11,875,000. This figure included the grants to the teaching hospitals provision for vocational education after the present academic year and £5,000,000 for the capital grants.

Dr. J. H. P. F. C.—The supply position for vacuum flasks is still at a low level. The scheme for one pint thermos flasks cannot be dropped. This scheme according to Sir Stafford Cripps, is a full account of the needs of agricultural and other rural areas as well as of the cases in which there are no other facilities for having a hot drink.

Dr. J. H. P. F. C.—The present production of streptomycin in Britain is very small. The Minister of Supply hopes that by June it will be about 250 grammes per month. The Medical Research Council is concerned with the use of streptomycin in certain types of bacterial infections.

Dr. J. H. P. F. C.—From November 1945 to February, 1946, 1,000 cases of measles in Greater Britain were compulsorily notified. Of these, 100 were found to be suffering from cerebral disease.

The Services

Major General W. Foot, M.C., late R.A.M.C. has been appointed Honorary Physician to the King in succession to Col. (Hon. Brig.) J. S. K. Boyd, O.B.E., late R.A.M.C., retired.

Col. J. Biggam, M.C., late R.A.M.C., has been appointed Honorary Surgeon to the King in succession to Major Gen. R. E. Barnsley, C.B., M.C., R.A.M.C. (ret.).

Major (Hon. Lieut.-Col.) H. Stevenson, R.A.M.C., has been awarded the Efficiency Medal (Territorial).

The President of the U.S.A. has conferred the following decorations in recognition of distinguished services in the cause of the Allies.

Legion of Merit Degree of Commander—Major-Gen. (Temp.) Sir Henry Letheby Tidy, K.B.E., late R.A.M.C.

Legion of Merit Degree of Officer—Col. D. G. Cheyne, C.B.E., M.C., late R.A.M.C., Brig. J. A. MacFarlane, O.B.E., E.D., R.C.A.M.C.

Bronze Star Medal—Col. (Temp.) H. H. Kenshole, D.S.O., T.D. Majors (Temp.) W. G. H. Allen and A. D. Robertson, R.A.M.C.

Medal of Freedom with Bronze Palm—Major (Temp.) G. A. G. Peterkin, M.B.E., R.A.M.C.

The King of Norway has conferred the King Haakon VII Freedom Medal upon Acting Air Cdre R. R. Macintosh R.A.F.V.R., in recognition of valuable services rendered in connexion with the war.

The Queen of the Netherlands has conferred the following decorations in recognition of distinguished services in the cause of the Allies.

Bronze Lion—Capt. J. W. Logan, D.S.O., R.A.M.C.

Bronze Cross—Major (Temp.) C. J. Longland, Capts. T. D. V. Swinseow and D. Wright, M.C., R.A.M.C.

CASUALTIES IN THE MEDICAL SERVICES

Died on Active Service in India on March 6 from injuries received in an accident—Capt. James Campbell Forfar, R.A.M.C.

DEATHS IN THE SERVICES

Col. EDWARD MAUDSLEY MORPHEW, CMG, DSO, died at Cromer on March 8 at the age of 79. A student of University College Hospital, London, he qualified M.R.C.S., L.R.C.P. in 1890. He retired from the R.A.M.C. in 1921, having seen active service in the Tihah campaign of 1897, the South African war, in which he received the Queen's medal with four clasps and the King's medal with two clasps and in the 1914-18 war, in which he was mentioned in dispatches and received the DSO. He was made a CMG in 1918.

AUXILIARY R.A.M.C. FUNDS

The annual general meeting of the members of the Auxiliary Royal Army Medical Corps Funds will be held at 11, Chandos Street, London W.1 on Monday April 14, at 5.30 p.m., when the annual report and accounts for 1946 will be presented and officers and auditors elected for 1947.

The Minister of Health trusts that local authorities will now resume the process, interrupted by the war, of establishing small homes for the aged, and he will consider schemes for the acquisition and adaptation of suitable premises even where priorities or compulsory purchase are involved. A number of such schemes have in fact already been approved. Success has been achieved where the numbers in these homes have been limited to 30 or 35 residents of both sexes carefully chosen to ensure congenial companionship where the maximum amount of freedom has been allowed to the old people where facilities for worship, recreation, shopping and other services have been readily to hand and where the site is well away from the public assistance institution. The present demand is for a greater degree of freedom in the residents' daily routine particularly in the institution and for easier and more frequent contact with the world outside. There should be visiting hours on each day of the week. Where practicable the residents who wish to do so should be allowed to use their own clothes. Each resident should have a wardrobe or locker with keys, where personal clothes and private possessions may be kept in safety. In the past too much caution has been exercised "in the interests of the aged" when framing the rules for the old people's activities both inside and outside the institution. More freedom should be allowed even if the risks are greater.

EPSOM COLLEGE

The council of Epsom College will shortly proceed to award St Ann's Scholarships to girls attending Church of England schools. Candidates must be fully nine and under sixteen years of age and must be orphan daughters of medical men who have been in independent practice in England or Wales for not less than five years. The value of each scholarship is dependent upon the means of the applicant and the locality and fees of the school selected.

Pensions are also available from the Fund of the Royal Medical Foundation for impecunious medical men or their widows, and Foundation scholarships, providing education, clothing, and maintenance free of cost, for the sons of necessitous medical practitioners. Application forms are available from the secretary, Epsom College, Surrey.

Medical News

There will be a discussion meeting of the Medical Society of the L.C.C. Service on Thursday, April 3, at 4.15 p.m., at the County Hall, Westminster Bridge, S.E. Dr McCartney will open a discussion on 'The Uses of Photography in Medicine'. A number of films made by members of the society will also be shown.

A Pasteur Exhibition will be held at the Science Museum, South Kensington, from April 10 to May 26. Arranged with the assistance of the Cultural Relations Department of the French Foreign Office by the Palais de la Découverte in Paris where it has recently been on show, it will include a chronological account of the chemical and biological work of Louis Pasteur on fermentation, putrefaction, the spontaneous generation of life, and on the germs of numerous diseases of men, animals, and plants. A section of the exhibition will deal with the Pasteur Institutes established throughout the world for the preparation of serums and vaccines for the combating of disease epidemics. The museum will be open, admission free, from 10 a.m. to 6 p.m. on weekdays, including Saturdays and bank holidays, and from 2.30 p.m. to 6 p.m. on Sundays.

The 19th annual dinner of the Great Ormond Street Dining Club will be held at the Savoy Hotel on Friday, April 11, at 7 p.m., with Dr Harold Sington in the chair. All members who wish to attend are asked to communicate with the honorary secretary, Hospital for Sick Children, Great Ormond Street, London, W.C.1.

The British Red Cross Society will hold its Easter conference at Exeter University, and has arranged to hold a conference in the North of England on July 4-7, when Durham University is willing to accommodate 150 delegates.

Speaking on 'The Study of Epidemic Influenza' at the Royal Institute of Public Health and Hygiene on Feb. 19, Prof. C. H. Stuart Harris said that the modern study of influenza had begun fifteen years ago with the first laboratory transmission of the disease to the ferret. Technical advances since then had brought the study of the influenza virus within the scope of most well equipped laboratories. Of chief importance had been the proof of the existence of two independent influenza viruses, A and B, and the utilization of the allantoic and amniotic cavities of the chick embryo for cultivation of the virus and demonstration of its specific haemagglutinin (Hirst phenomenon). Epidemics of influenza were studied in order to demonstrate the type of virus concerned and to differentiate influenza from outbreaks of other types of respiratory tract disease. In the past epidemics of influenza virus infection among semi-isolated communities had exhibited a striking variation in incidence, being sometimes a few sporadic cases and at other times explosive outbreaks. When the incidence of influenza in the general population was studied by means of mortality statistics a correlation was found to exist between widespread epidemics and the demonstration of influenza virus infection in the laboratory. There was evidence of a periodicity of influenza virus infection with cycles at well defined intervals. Thus some power of prediction of the likelihood of future epidemics now existed, but the intensity of the future outbreak was still a matter of conjecture. Experimental study of influenza by the inoculation of human volunteers with cultures of influenza virus had been developed considerably during the war both in order to yield information concerning immunity and as a test of the efficacy of artificial immunization. The results provided a basis for field trials of immunization in advance of epidemics of influenza, and the success of these trials had suggested that influenza was a preventable disease.

Mr A. W. McKenny Hughes, D.I.C., who is on the staff of the Natural History Section of the British Museum, has been appointed Hon. Entomologist to University College Hospital.

Sir John Boyd Orr, Director General of the F.A.O., has announced that the World Food Council will probably be set up at Geneva in August.

The first annual meeting and dinner of the Airborne Medical Society were held on March 15. Brig A. A. Egger was elected president and Mr G. Rigby Jones honorary secretary. It is proposed to arrange a dinner annually on the evening of the England-Scotland 'rugger' match and a lunch after the annual Airborne Forces memorial service. Gen. Sir Alexander Hood, who was present as a guest, pointed out that many in the room had been pioneers in developing and practising airborne warfare, and Gen. Urquhart suggested that they could render valuable service to the territorial airborne division now being formed. Besides combatant units that would require medical personnel there would be three field ambulances, located probably at London, Liverpool, and Sheffield.

The annual dinner of the Association of Certifying Factory Surgeons was held at the Café Royal, London, on March 20. Mr George Isaacs, Minister of Labour and National Service, had accepted an invitation to attend but was unable to do so. Proposing the toast of the visitors Dr M. W. Paterson suggested that the 84-hour week worked by most general practitioners might be held to entitle them to the same pensions as those laid down for commissioners and deputy commissioners under the Industrial Injuries Act. In an eloquent reply Mr James Griffiths, Minister of National Insurance, referred at some length to this Act, which gave doctors far greater responsibilities than any of the Workmen's Compensation Acts. He described the Act as 'a new chapter in the treatment of the men and women who serve the industries of the nation'. Dr R. Nightingale, who presided, proposed the toast of the Factory Department of the Ministry of Labour. In the absence of the Minister, Dr E. R. A. Merewether replied. Finally, Dr David McKail responded to Dr Charles Hill's toast 'The Association of Certifying Factory Surgeons'. Dr Hill mentioned the many links between the Association of Certifying Factory Surgeons and the B.M.A.—links which he hoped would be strengthened in the future. He took the view that the aim of both associations must be the provision of the same health service for the smaller factories as was achieved at its best in the larger factories.

On the advice of the Food Rationing (Special Diets) Advisory Committee, the Minister of Food has decided that persons suffering from active tuberculosis and actinomycosis who are granted a priority supply of milk shall also be granted an additional allowance of one ounce of bacon weekly in order to restore to them the recent cut in the ordinary consumer's bacon ration from three ounces to two ounces a week. These invalids are being invited in the present instance to apply at local Food Offices for the additional allowance. In future the medical certificate of classification will provide the necessary authority for issue.

Each year scholarships in Britain are awarded to students usually postgraduates, from a number of countries overseas by the British Council. Since the end of the war scholarships have been offered in return to British graduates by Czechoslovakia, Sweden, the Netherlands, and Finland. Ten scholarships of one year's duration have been awarded by the Czechoslovak Ministry of Education, two scholarships for one year each by the Swedish Ministry of Education and the Swedish Institute for Cultural Relations (including one to J. N. Mickelson, M.D., for the study of diseases of the heart and chest), three scholarships for one year and four for one term by the Netherlands Ministry of Education, and one scholarship for one term by the Finnish Ministry of Education.

A unit for the investigation and treatment of rheumatism under the auspices of the British Legion has, since June, 1946, been in operation at Fairfield Hospital, Letchworth, Herts., where there are 50 beds for this purpose. Fairfield Hospital is the country annexe of the Royal Free Hospital. The unit at Letchworth owes its existence to the initiative of the governing body and medical committee of the Royal Free Hospital.

St George's Hospital is to move from its present site at Hyde Park Corner to the Springfield Estate at Wandsworth. The new building will house 1,000 beds. St George's was founded in 1733 in Lanesborough House on fields overlooking Hyde Park, and was rebuilt on its present site at the 'centre of London' just over 100 years ago.

As a result of representation by local authorities the Secretary of State for Scotland has agreed to the introduction of a standard test for milk apart from designated and heat-treated milks. The test to be used is the methylene blue (Hiscox) test. Milk failing to pass the test will result in investigation into the conditions of its production and handling.

In our account of the British-Swiss Medical Conference in the *Journal* of Sept. 28, 1946, we stated that Mr John Hunter was unfortunately taken ill during the Proceedings. We are glad to learn that he is now back at work.

Dr Doris Odium has been elected a Corresponding Member of the Swiss Psychiatric Association.

In SIMPLE INSOMNIA....

When the prescriber's aim is to induce tranquil sleep rather than prolonged hypnosis, the special characteristics of 'Tabloid' brand Cyclobarbitone deserve consideration. Unlike the longer-acting members of the barbituric acid group, Cyclobarbitone rapidly produces a short-lived hypnosis which passes imperceptibly into sleep, the patient wakes refreshed and free from drowsiness. In the treatment of insomnia, and as a mild sedative for neurasthenic and psychotic patients, Cyclobarbitone can be given for long periods without cumulative toxic symptoms.

An outstanding advance in
liver therapy

HEPAMINO

The original pro colysed whole liver preparation developed and introduced by The Evans Biological Institute.

For the treatment of all macrocytic anaemias (including refractory anaemia) nutritional deficiencies and as a supplementary food in convalescence.

Hepamino is a soluble, pre-digested preparation of whole liver in granular form for oral use.

It contains the haemopoietic factors (including folic acid) essential amino acids and water-soluble members of the vitamin B complex derived from raw liver.

(The representative composition will be supplied on request)

*Brit. med. J. 1944, 1, 655

Ample supplies of Hepamino are available and with the relaxation of the restrictions on the use of liver it may be freely prescribed whenever desired.

In containers of approx. 5 oz.

THE LARGEST ORGAN IN THE BODY

Irradiation is a method of administering medicine through the skin—the largest organ in the body—in a form readily absorbed by the organism. As ultra-violet energy, radiation evokes tonic reactions which affect all the processes of metabolism and extend to the remotest cells in the system.

Infra-red and luminous rays produce local hyperæmia, and speed up the processes of nutrition and phagocytic healing. Administered in concert, both groups of radiations interact in a harmony equivalent to sunshine, and are invaluable in a great variety of conditions. The Duo-therapy Unit affords full facilities for the application of every form of actinic irradiation—ultra-violet, radiant heat, infra-red can be used separately or conjointly, with absolute accuracy, convenience and constancy.

Our brochure No. 147 contains a description of the unit, with illustrations, output diagrams and details. It can be obtained free on request by professional inquirers.

The Dakin and West Erythropoietic Fraction of Liver

The clinical efficacy of Anahæmin B D H in anæmia is remarkable even in the presence of factors tending to limit its activity.

For example, in some cases in which iron is not freely abundantly available, erythropoiesis induced by Anahæmin B D H may temporarily outstrip hæmoglobinisation, producing a hypochromic anæmia. The provision of an iron diet during treatment is usually sufficient, however, to provide all the necessary iron and other hæmatinic substances required to produce a balanced and prompt erythrocytosis in response to treatment with Anahæmin B D H. Further information is available on request.

Anginal Pain

In view of the now generally accepted theory that the pain of Angina Pectoris is due to myocardial anoxæmia, a potent coronary vasodilator such as Cardophylin may be of value in relieving the anoxæmia when this is due to an inadequate blood supply to the myocardium, especially where coronary constriction is the main factor in interfering with the blood supply.

* Measles and whooping-cough are not notifiable in Scotland and the returns are therefore an approximation only.

† Includes primary form for Eireland and Wales London (administrative county) and Northern Ireland

‡ Includes puerperal fever for England and Wales and Eire

Return of births and deaths for Eire for week ended March 8 is not yet available

EPIDEMIOLOGICAL NOTES

Discussion of Table

In England and Wales a decrease in notifications was recorded for measles 1,200, dysentery 23, and acute pneumonia 23 while an increase was reported for whooping-cough 171 and scarlet fever 50

The rise in the incidence of whooping cough was mainly confined to London and the south east and south midland counties, 168 more notifications were recorded in these areas than in the preceding week, but no large local variations occurred. Only small fluctuations were reported in the local trends of scarlet fever

A small decrease was recorded in most areas for cases of acute pneumonia, the only exception of note being an increase of 27 in London. The only appreciable change in the local returns of diphtheria was a decrease of 14 in Lancashire. The largest falls in the notification of measles were Lancashire 440, Middlesex 181, Staffordshire 179, Nottinghamshire 133, Warwickshire 121, and Devonshire 107 counties with an increased incidence included Yorkshire West Riding 94, Derbyshire 62, Somersetshire 56, and Glamorganshire 45

An outbreak of dysentery was reported in Dorset, Poole M.B., affecting 12 persons. The only other important centres of dysentery were Middlesex 12 and London 11

In Scotland a decrease was recorded in the notifications of scarlet fever 29 and of diphtheria 12. There was an increase in cases of acute primary pneumonia 26 and dysentery 22. The notifications of diphtheria have declined continuously for the past month and the 34 cases during the week are the smallest total yet recorded, half of these cases were notified in Glasgow. The increase in the incidence of dysentery was due to its re-appearance after one week's interval, in Banff county where 20 cases were notified this week.

In Eire a rise occurred in the incidence of primary pneumonia 34 and of whooping cough 23. Notifications of diarrhoea and enteritis were 12 fewer than in the preceding week. The rise in the incidence of whooping-cough was due to the experience of Dublin C.B., where cases increased from 62 to 87

In Northern Ireland a further fall of 29 was recorded in the outbreak of measles in Belfast C.B. Diphtheria notifications which had been at a constant level of 6 cases per week rose to 12 cases

Week Ending March 15

The notifications of infectious diseases in England and Wales during the week included scarlet fever 1 336, whooping cough 2 407, diphtheria 184, measles 11 269, acute pneumonia 1 076, cerebrospinal fever 107, dysentery 73, smallpox 2, paratyphoid 5, typhoid 6. Deaths from influenza in the 126 great towns numbered 80

Universities and Colleges

UNIVERSITY OF LONDON

CHANCING CROSS HOSPITAL MEDICAL SCHOOL

The pre-clinical departments of Charing Cross Hospital Medical School are to be reopened. The school ceased to teach anatomy and physiology in 1911 and entered into agreements with King's College, London, whereby students of the school attended the college for this instruction, an arrangement which has continued to date. As the accommodation in the medical schools throughout the country is inadequate for the number of students wishing to study medicine the revival of the departments in the school, by absorbing an additional 45 students each year will help to meet the deficiency. It is hoped that the repair of the damage to the school buildings, suffered as a result of enemy action during the war, will be completed in time for the departments of anatomy and physiology to be reopened at the beginning of the next academic year in October. Opportunity will be taken at the same time to admit women students to the clinical as well as to the pre-clinical courses

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

A—Ethisterone is a steroid compound whose chemical structure is similar in type to that of progesterone and testosterone.

Other names for it are anhydro hydroxy progesterone ethinyl testosterone and pregnenolone. Its biological actions, according to animal experiment, resemble in some respects those of progesterone and in others those of oestrogens and of androgens. Among other things it has been shown that in rabbits ethisterone can produce progestational changes in the oestrogen primed endometrium and that it prevents abortion which ordinarily follows ovariectomy during pregnancy in these animals. It is on such evidence that it is used in place of progesterone, or as a supplement to it, in cases of habitual abortion. Its advantage over progesterone is that it is effective by the oral route. On the other hand, its biological activity is comparatively weak, and progesterone given by injection is six to ten times more effective. Large doses of ethisterone are therefore required, and although it is widely used in clinical work it is doubtful whether its practical value has yet been established.

Instruction about Menstruation

Q—Could you recommend a book dealing with the physiology of menstruation and suitable for a girl of 12 years? I would prefer one containing diagrams.

A—I do not know of any book on menstruation suitable for reading by a girl of 12 and if any are available the wisdom of giving them to a girl of that age is open to question. She should not be encouraged to concern herself with the details of anatomy and physiology but should be told only the general principles governing menstruation and its management. This information is best imparted verbally and informally, as the occasion arises, by informed parents, or sometimes by the family doctor or school teacher. See also a reply to a question published in the *Journal* of Oct 6 1945 (p 483).

Carcinoma at Site of Insulin Injection

Q—Is anything known of the development of carcinoma at the site of injection of protamine zinc insulin?

A—So far as is known a carcinoma has not developed at the site of injection of protamine zinc insulin though atrophy of the fat may occur if repeated injections are made in the same place. It is advisable to change the site of injection every day.

Causes of Anosmia

Q—A middle aged woman has lost her sense of smell but has had a musty sweet odour in the nose for six months following an attack of influenza. She has since been free from colds. There are no other signs or symptoms. What line of investigation or treatment should be followed?

A—The patient has either a sinusitis which has not been previously located and may be in one or other antrum or an atrophy of the olfactory nerve following influenza. In any case the sinuses should be x-rayed.

Erythromelalgia at the Menopause

Q—Until the age of 45 when the menopause started a woman had severe chilblains every winter since then she has had none. She is now 49 and for the past three years has had increasingly painful burning of the feet as soon as she gets warm in bed with every sign of extreme local vasodilatation. Her blood pressure is 190/100 mm Hg and her last period was two years ago.

A—Although the menopause seems to have precipitated the vascular change in the feet this is not necessarily so, and some features of the case suggest that the two conditions are not directly connected. Thus a change in the circulation of the feet evidently began at least two years before menstruation ceased, and whereas the climacteric disturbance of the vasomotor system, as manifest by hot flushes, seems to be clearing up the vascular upset in the feet is getting worse. It is therefore unlikely that oestrogenic or other hormone therapy will be of any value. The description is fairly typical of one type of erythromelalgia in which the symptoms are brought on by heat rather than posture. If the patient has arterial disease associated with the hypertension this might be an important aetiological factor, and investigations from this standpoint should be carried out. Unless an underlying cause such as

this can be found the treatment of erythromelalgia is not very satisfactory, but, apart from simple treatment such as elevation of the feet and reducing the number of bedclothes, calcium in large doses and quinine sometimes appear to be helpful.

Cold Urticaria

Q—A healthy girl of 19 has for the last five years been subject to attacks of urticaria on exposure to cold. The rash is typical and spreads rapidly over the body. It fades within half an hour if she gets warm. Treatment by calcium injections has had no effect.

A—Cold urticaria indicates a peculiar individual sensitivity to mild exposure to cold or to a certain range of temperatures. In these individuals the slight injury provokes an abnormal quantity of a histamine-like substance in the skin which determines the local and general reaction by urticaria. The susceptibility may date from puberty or sometimes follows an illness, such as influenza. It commonly lasts for a number of years and eventually disappears. The usual lines of treatment have not in the past been of much avail but it is likely that the recently introduced anti-histamine products (for example benadryl) may control the attacks.

Mongolism and Thyroid Deficiency

Q—What is the earliest age at which treatment with thyroid should be started for mongolian idiocy? What is the dosage and what if any are the precautions that should be taken? Is it of much use?

A—Mongolian idiocy is not caused by a thyroid deficiency, therefore treatment with thyroid will not be of benefit. It is remotely possible that a mongolian idiot might also be a cretin, although no such combination has ever been reported. In these circumstances the cretinism should be treated with thyroid, starting with 1/4 gr (16 mg) daily in early infancy and later increasing the dose to 1/2 gr (32 mg).

Heat Reflection

Q—Is there a suitable material for covering the screen behind an invalid's chair so as to reflect the heat from the fire? Can walls or ceilings or even curtains be made to reflect heat?

A—A bright polished surface reflects most and absorbs least. White and light-coloured materials reflect most, and dark and black materials absorb most. A dark material lining an invalid chair will absorb more from a fire and become warmer while a polished metal screen encircling the chair will reflect the heat of the fire on to it. On the other hand, a dark screen will become warm and warm the surrounding air.

INCOME TAX

All inquiries will receive an authoritative reply but only a selection can be published.

Residence Abroad

***COLONIAL** is shortly taking up an appointment abroad. He has an income arising in this country—£360 gross taxed at source plus £22 10s which is not taxed and which we assume to be derived from 3½% War Stock. Will he be able to reclaim the tax paid in the United Kingdom?

***Not entirely.** Assuming that "Colonial" is not retaining a residence in this country, he will be entitled, as a British subject residing abroad, to claim a proportion of the reliefs claimable by residents here. For instance, his British income (excluding the war loan interest on which he will be able to claim exemption) will be about one half the colonial income, and he will therefore claim one-half of the reliefs due in respect of personal allowance, the reduced rate applicable to the first £125 of taxable income, etc.

Cost of Telephone

R holds an appointment—his duties require him to be on call though the majority of the calls are private ones. What can he claim as a deduction from his salary?

***The current costs of his telephone—i.e., total cost less any "instalment" expenses—in the proportion of the "employment" calls to the total. No doubt the amount will have to be estimated.**

Letters and Notes

Twelve Toes

Dr ARDESHIR K TURNER (Bombay) writes I am tempted to bring this case of 'nature's freak' before the medical practitioners of England and other countries. The photo is that of a Hindu

labourer (household worker) aged 25. He has two big toes on both his feet and can walk without the least difficulty or pain. His hands and fingers are all right. He is a bachelor. None of his relations shows this abnormality.

Prognosis of Hypertension

Dr W WEISS (London NW6) writes I read Dr V C Medve's letter (Feb 15, p 269) on the 'Prognosis of Hypertension' and learned that apparently great conflict has arisen with regard to the fact that the blood pressure in old people is above the arithmetical average. A blood pressure to be regarded as 'high' in middle age may be low in old age. It is not the reading of the blood pressure as such which has to be taken into account when a prognosis is to be made, the problem is, how does the motor the heart, react to the blood pressure level? The heart certainly will often have to work harder when a blood pressure rises, and it makes no difference to the organ whether the blood pressure rises in younger days (hypertension) or whether the rise occurs (physiological) in older days—the heart will be urged to work harder. And so at best it depends entirely on the vitality or muscle power of the heart muscle whether the old patient will have to be recognized as a 'hypertonic' or not.

Hospital Bureaucracy

Mr G H CAIGER FRCS (S Africa) writes The African servant of a friend of mine fell off a bicycle returning from a garden on the outskirts of the town. When he had not returned before dark the mistress learned from the police that the boy had been admitted to the local Government hospital with a fractured forearm (lower third of the right radius). This occurred on a Thursday. She rang up and also visited the hospital to find out and see how the boy was. Someone in the 'phone inquiries' seemed to think it very funny her asking about a patient and could be heard laughing and repeatedly saying 'poor Willie X'. As if once was not enough this was repeated again the next day on making inquiries, but the mistress's humour was by this time flagging somewhat. No radiographical examination had been made before the week end, and on the Monday the mistress was informed that the 'doctor' (H.S.) had been away for the week end. Being a trained nurse she repaired to the hospital to see if things could be expedited, and soon succeeded in demolishing the myth that the doctor had been away, and got an admission that he had been there all the week end. On the following day Tuesday, five days after admission she was informed on inquiry that the x-ray showed the bone in good position and it was not necessary to set the fracture. Till now only the temporary splint had been left on, the arm remaining painful. They could not say when he would be fit to discharge. Unhappy about the whole position and planning to leave on holiday on the Thursday, she suddenly in her extremity remembered a friend of her husband's in charge of a missionary hospital for Africans, and she repaired to him for advice. He is an American and so put his hand in his pocket from long usage, produced his car keys and said, 'Take my car drive down to the hospital get the boy discharged bring the x-rays and the boy to me. The boy was admitted, the fracture set under an anaesthetic and the arm put in plaster, and the boy was sent out that afternoon. The final result has been 100% and the boy has full use of the arm. It is easy to tell this little tale, which, although it concerns an African, may as easily apply to others before long. In my opinion it illustrates the difference between the bureaucratic ridden institution

and the hospital as those who know what it should be and as they would like to see it. Soon those who know the best tradition will not be there, or submerged beneath a sea of bureaucracy, as they fear their patients with them. This, as I see it, is the central fear of many that the belief in 'drive, organization, and will-power' does not build real systems of healing and endangers the finer spiritual qualities without which the best cannot be achieved or maintained.

Shadows under the Eyes

Dr HUGH A L O LATT (Liverpool) writes Shering Di Bernard Sweetman's interest (Feb 15, p 283), the one constant factor in those I have observed seems to have been emotional inhibition. It is most noticeable in young people with finer, softer skins and more resilient subcutaneous tissues, and three groups as examples come to mind: (1) Children prevented from free expression in play; (2) young people from 15 to 25 denied free social intercourse by too strict an upbringing; (3) students not taking sufficient physical and mental relaxation while swotting for examinations. Assuming the relative overworking of inhibitory impulses from the prefrontal gyrus makes increased blood drainage via the tributaries of the anterior cerebral veins one can postulate that some of these will be shunted via the anastomotic veins adjoining the anterior cerebral to the ophthalmic veins. The relative subcutaneous venous engorgement at the inner angle of the eye and on both eyelids is easily visible, but attention is focused on the area just beneath the eyes where the contrast with the skin of the cheek is so marked. The dramatized 'hollow eyes' of grief, anguish and villainy seem to be the sign in its most pronounced form.

Dr JOHN CAHILL (Middlesbrough) writes Referring to Dr Bernard Sweetman's inquiry (Feb 15, p 283) as to the causes, other than gross organic disease, of shadows under the eyes it appears that such shadows in the young are most frequently associated with fatigue in a nervous child.

Cracked Nipple

Dr D RUD TWEDIE (Sungei Siput, Perak, Malaya) writes Having failed with all the usual nostrums to disperse a painful crack in the nipple of a nursing mother I tried the effect of applying after feeds a drop of a strong solution of penicillin (20,000 units to 1 ml), and was astonished and pleased to find that the crack granulated up and disappeared in about 72 hours.

Penicillin for Colds

Dr J A ROUTH (Brighton) writes In reply to your correspondent (March 1) who asks if penicillin has been tried for colds I have tried it on myself and family with great success. The technique is simple. I use the ointment in a tube with a small nozzle and squeeze a small amount into each nostril, massage the nose slightly and then sniff up the ointment. The effect was most encouraging—the sneezing and running of the eyes and nose stopped immediately and the extension of the coryza to the bronchial tubes was arrested. This treatment should be investigated.

Disclaimer

Dr R CUDDEFORD (Cross in Hand Sussex) writes I am the doctor mentioned in an article on a three pound baby in the *Sussex and County Herald* dated Feb 14, 1947. I was not aware that this was printed in a public newspaper until it was pointed out to me. I am in no way responsible for the publicity, which is apparently the effect of the grateful parents.

Correction

In the reply to a question about 'dilatant' (Feb 15, p 28) we should have made it clear that 'dilatant' is the proprietary name in America for sodium diphenylhydantoinate, introduced many years ago by Parke Davis and Co., following the work by Merrifield and Putnam to which reference was made (*Science* 1937, 85, 57). In this country 'dilatant' became 'epanutin', and the drug sold by other firms as phenytoin soluble and as sodium diphenylhydantoinate.

PETHIDINE IN LABOUR: RESULTS IN 500 CASES

BY

JOSEPHINE BARNES, D.M., MRCP, FRCS, MRCOG

Assistant, Obstetric Unit University College Hospital

The search for the ideal analgesic agent for use in obstetrics has continued for very many years and innumerable agents have been recommended. Pethidine is a comparative newcomer to this field, and although it has already received extended trial its value, uses, and limitations do not seem to be as well known as they should be. This article embodies the results of its use in over 500 cases in the Obstetric Unit at University College Hospital between the years 1942 and 1946.

Chemistry and Pharmacology of Pethidine

Pethidine is 1-methyl-4-phenyl piperidine-4 carboxylic acid ethyl ester hydrochloride. In Germany, where it was originally discovered and in South America it is known as "dolantal" or "dolantin". In the USA and Canada it is known as "demcrol," and it has also been known as S-140 and D-140. It is unfortunate that these different names have come into use in different countries, since it leads to confusion. The original description was given by Eisleb and Schaumann (1939), who introduced it as a synthetic substitute for atropine. They found that it not only possessed spasmolytic powers similar to those of atropine but also was antagonistic to acetylcholine, tended to depress the action of smooth muscle, and had a marked analgesic effect. Dietrich (1939) as a result of clinical trial found pethidine useful as an antispasmodic and analgesic.

Duguid and Heathcote (1940) found that pethidine has no haemolytic effect on erythrocytes and no effect on unicellular organisms. They noted a depression of all types of muscle—cardiac, striated and non striated. Pethidine also causes a non-toxic fall of blood pressure, depresses the respiratory centre, and acts as an analgesic by relieving spasm of smooth muscle and by raising the pain threshold. Gruber, Hart and Gruber (1941) confirmed the fall in blood pressure, which they showed was due to preliminary vasodilatation. They found respiration temporarily diminished in depth and frequency, and that the effect on smooth muscle was unpredictable. No effect was noted on intact smooth muscle contractions were maintained, and the analgesic effect was not due to spasmodic. Generally, the effect on the uterus was one of stimulation, though to a less degree than with posterior pituitary extract. Roehrschild (1941) stated that pethidine is a powerful analgesic with an action like that of morphine. It stimulates rather than depresses the central nervous system. No effect was observed on the pulse or the pupils, but the fall of blood pressure was noted and also depression of respiration, though only with large doses. Batterman (1943) confirmed the above findings and stated that pethidine is more valuable for relieving pain of visceral origin than that of peripheral origin. He noted a tendency towards dizziness and faintness and doubted if the drug was safe for ambulatory patients. Syncope was occasionally seen. Batterman and Himmelsbach (1943) studied the effects of pethidine and compared them with those of morphine. They tested the analgesic effect by raising the pain threshold, using the method

of Hardy, Wolff, and Goodell (1940). Batterman and Himmelsbach found that the pain threshold was raised to a maximum in one hour and that the effect lasted up to six hours. The usual duration of analgesia was about three hours. They found that 50 mg of pethidine was equivalent to 22 mg of codeine and to 17 mg of morphine, but that the duration of its effect was shorter. They confirmed its value in visceral pain, especially in the colicky type, and quoted a personal communication from G. Woodby, who found no effect on the action of the uterus in labour. They considered the addiction liability less than that of morphine.

The question of the liability of pethidine to cause addiction was studied by Himmelsbach (1942), who stated that it was much less than with morphine. He observed tremor when pethidine was given over a long period. Andrews (1942a) using patients addicted to morphine, found that a tolerance is developed to the pain-threshold-raising effect that is maximal at eight weeks and is maintained for 30 days after discontinuance. Andrews (1942b) also found that morphine addiction causes changes in the electroencephalogram and that pethidine in very large dosage has powerful cortical effects, which are pleasant and might lead to addiction. The doses given were enormous—in the region of 3,000 mg. Yonkman, Noth, and Hecht (1944) noted that pethidine is safe, is readily absorbed, and possesses a weak atropine-like action with a strong papaverine-like effect on smooth muscle. The effect was more intense in the presence of spasm or stimulation. Noth, Hecht and Yonkman (1944) noted analgesic effects similar to those observed by Batterman and Himmelsbach (1943). They found a slight tendency to addiction.

Uses of Pethidine in Medicine, Surgery, and Gynaecology

Pethidine on account of its analgesic and spasmolytic effects has been used for relief of pain in medical, surgical, and gynaecological conditions. Christie (1943) gave pethidine by mouth to 335 cases, comparing its effect with that of tab. codein. He found that in 46% of cases pethidine was more effective than the codeine preparation, in 21% as effective, and in 33% it was ineffective. He found the analgesic effect less than that of morphine but generally enhanced when pethidine was given by injection. Branwood (1943) described clinical trials with pethidine, and concluded that it was valuable for biliary, renal, and intestinal colic and for hypertensive headaches. It was useless for neuritic pain. Sleep and drowsiness tended to occur independently of pain relief. A fall in blood pressure was noted, especially when pethidine was given intravenously, but no toxic effects were observed and no changes in blood or urine. FitzGerald and McArdle (1943) used pethidine in twelve neurological cases and found the effect comparable with or superior to that of morphine.

Objectionable side-effects such as giddiness, nausea, and faintness were noted when pethidine was given intravenously

Rovenstein and Batterman (1943) described the use of pethidine with scopolamine for premedication. They found that patients tended to complain of thirst and dryness of the mouth. They noted, however, that this combination provides psychic sedation, does not depress respiration so much as morphine, facilitates induction of anaesthesia, has more effect in drying secretions than morphine, has fewer undesirable side-effects, and reduces the amount of anaesthesia required as much as morphine. Batterman and Mulholland (1943) studied the effect of pethidine as a substitute for morphine for post-operative pain. They found it satisfactory, though side-effects such as dizziness and nausea were noted. These might partly be due to the anaesthetic. The action was short—only about two hours. They prefer pethidine to morphine since it rarely causes respiratory depression, has an antispasmodic effect, dries mucous secretions, and does not suppress the cough reflex.

Sostmann (1940) used pethidine as a substitute for morphine in gynaecology. He found that the minimum effective dose was 25 mg by mouth, 50 mg by injection, and 100 mg per rectum. He observed a good analgesic and spasmolytic effect. Hecht, Noth, and Yonkman (1943) studied the general effects of pethidine in 111 patients. They noted certain toxic effects, including dizziness, nausea, vomiting, dryness of the mouth, and euphoria. They found no effect with normal dosage on the blood or electroencephalogram, and concluded that pethidine can be used as a substitute for morphine. Hori and Gold (1944) reported a good effect from the use of pethidine in 2,000 cases, though this was weaker and of shorter duration than that of morphine. In post-operative cases there was less need for catheterization and the constipating effect was less than when morphine was used. Pethidine can be combined with scopolamine and with the barbiturates. In 50 obstetrical cases good sedation was obtained in 30, but the effect was better when pethidine was given with scopolamine.

Pethidine in Obstetrics

The first account of the use of pethidine in labour was that of Benthin (1940), who described its use in 400 cases. Pethidine was given alone in 250 cases and combined with amidopyrine in 150. The optimum dose was found to be 100 mg given by intramuscular injection and repeated once or twice if necessary. The course of labour was uninfluenced and the child was not affected. The same author (Benthin, 1942) recommended an initial dose of 100 mg combined with rectal administration. He claimed that pethidine reduced the duration of labour in 30- to 40-year-old primiparae to 13½ hours. He found that pethidine could usefully be combined with oxytocics such as "thymophysin". Sonnek (1941) stated that labour was facilitated by the use of pethidine, and Fuchs (1941) claimed good results from the use of twilight sleep induced by pethidine and an intravenous barbiturate.

Gilbert and Dixon (1943) administered pethidine to 150 women in labour. The drug was given alone to 54 primiparae, the highest dose used being 650 mg and the lowest 100 mg. The average total dose was 294 mg. The average time elapsing between the last dose of pethidine and the end of labour was 2 hours 42 minutes, and the average total length of labour 11 hours 18 minutes. In 62 primiparae pethidine was used in combination with "seconal" (sodium propyl-methyl-carbinyl allyl barbiturate). The average duration of labour and the length after the final dose were similar to those in cases where pethidine was

given alone, and 72% of patients gained satisfactory analgesia with pethidine alone, though in no case was there amnesia. When pethidine was combined with "seconal" satisfactory amnesia could be obtained only with large doses—4½ gr (0.29 g) or more—of seconal. Toxic effects in the mother included dizziness and lightheadedness, also thirst and dryness of the mouth when a general anaesthetic was given as well. No effect on the third stage of labour was noted. Pethidine given alone had no apparent effect on the baby, but when combined with other methods, especially barbiturates, a slight to moderate depressant effect was noted, and treatment for foetal apnoea was necessary, though there were no foetal deaths from this cause. Gilbert and Dixon suggest as a programme for the conduct of labour that three 100 mg doses should be given in the early stages and that the pethidine dosage should be completed early in labour. Amnesia may be added with other drugs when necessary.

Roby and Schumann (1943) presented a preliminary report of the use of pethidine combined with scopolamine in labour in 112 cases. They gave an initial dose of 100 mg of pethidine, with 1/100 gr (0.65 mg) of scopolamine, followed by 1/100 gr of scopolamine one hour later. Schumann (1944) gave a further report on 1,000 cases. These authors claim satisfactory amnesia in 70.5% and a shortening of labour by 2½ hours in primiparae and 1½ hours in multiparae. In patients expected to deliver themselves quickly, intravenous administration was used with no demonstrable ill effect, except for transient nausea. Of 37 patients delivered without anaesthesia 79% could recall no pain whatever. No demonstrable effect was noted on full-time or premature babies. Schumann claims that pethidine combined with scopolamine is superior as an obstetric analgesic to others in common use.

The following scheme of dosage is recommended. An initial dose of 100 mg of pethidine and 1/100 gr (0.65 mg) of scopolamine is given. Forty-five minutes later a further 1/150 gr (0.43 mg) of scopolamine is given, and 100 mg of pethidine with 1/200 gr (0.32 mg) of scopolamine four hours later. This is followed as required by 100 mg of pethidine every four hours and 1/200 gr of scopolamine every three hours. Mackenzie (1943) described two cases in which 50 mg of pethidine hastened dilatation and relieved distress in the course of prolonged labour.

Gallen and Prescott (1944) described clinical studies in 150 cases. They gave 200 mg of pethidine alone or in combination with scopolamine or with a bromide chloral and-opium mixture ("mother's mist"). They found that pethidine acts in 15 minutes and the effect lasts three to four hours. Amnesia was noted in only one case where morphine and scopolamine were also given. The duration of labour was apparently prolonged, but the forceps rate was 10%—not a significant increase. Toxic reactions included vomiting, rise of blood pressure, dizziness, vertigo, and dryness of the throat, but the pethidine was given by the intravenous route. Nine babies required resuscitation, and these authors doubt whether pethidine should be given within 2½ hours before delivery is expected.

Cripps, Hall, and Haultain (1944) in a report of 102 cases concluded that although pethidine is not the ideal obstetrical analgesic it fulfils many of the conditions required of such an agent. It is not always successful in producing analgesia, but no undue excitability was noted. Amnesia occurred only when hyoscine (scopolamine) was given as well. Pethidine was found useful for premedication for caesarean section under local analgesia in six cases. Spitzer (1944) described a series of 80 normal mothers in whom all but 10% received satisfactory relief

at pain in labour with pethidine. The oral route was used and doses of 50 mg initially, followed by 25 mg, were given. No side-effects were observed. Spitzer claims, though without statistical evidence, that pethidine has a remarkable shortening effect on normal labour. Venters (1944) described a routine for labour where a bromide and chloral mixture was combined with diamorphine (heroin). Recently good results had been obtained by substituting pethidine for heroin, either entirely or in part. Steinberg (1945), in describing 400 cases where pethidine and scopolamine had been used in labour, noted three cases in which oedema of the uvula occurred, one having oedema of the glottis as well. All three exhibited a cutaneous sensitivity to scopolamine, as did a fourth case in which oedema of the uvula occurred after the use of seconal and scopolamine. While not completely relevant to the discussion of pethidine in labour, this represents a complication of the use of scopolamine that might well prove dangerous.

Lull and Hingson (1945) describe pethidine as one of the safer drugs for obstetric analgesia, though they believe that depression of foetal respiration occurs comparable to that present in the mother. Less narcotization of the baby is seen than with morphine. They recommend the combination of pethidine with scopolamine or barbiturates.

It will be seen from the review of the uses of pethidine that it promises well as an obstetric analgesic, though it does not gain universal or unqualified approval. Its chief advantage seems to lie in its relative safety to mother and child and in the relative rarity of toxic effects. It certainly deserves extended trial, and the object of this paper is to present results in such a trial, to assess its scope and limitations in obstetrics, and to make recommendations for its use in the future.

Clinical Results

Pethidine was first used for obstetric cases in the Obstetric Unit at University College Hospital in 1942. In order to establish the safety of this then relatively new drug a preliminary trial was carried out in 47 cases using doses of 50 mg. No toxic effects were noted, but it seemed that this dosage was inadequate.

Between 1942 and 1946 a full trial was given in 500 labours. Pethidine was not administered to every patient in labour, but only to those who appeared to require a sedative or analgesic. These cases are thus to some extent selected, since patients who had easy and relatively painless labours did not receive pethidine. The dose used was 100 mg given by subcutaneous or intramuscular injection, and repeated as required. In many cases pethidine was combined with other sedatives and analgesics, patients receiving nitrous oxide and air analgesia or "trilene" in the later stages of labour. In a few cases where pethidine appeared to be insufficient, morphine or papaveretum (omnupon) was given later in labour. No case received hyoscine since it was desired to ascertain as far as possible the effects of pethidine alone.

This series of 500 cases included eight pairs of twins, so that 500 mothers gave birth to 508 infants. There were 479 primigravidae and 21 multiparae. The total dosage given was as follows:

4 mothers received 100 mg	9 mothers received 400 mg
124 " 200 "	2 " 500 "
1 mother " 250 "	1 mother " 600 "
14 mothers " 300 "	

A single injection of 100 mg was adequate for the majority of labours, and a high proportion of the remainder required only two doses. Table I shows the method of delivery in these 500 cases.

TABLE I—Method of Delivery

	Primigravidae	Multiparae
Spontaneous vertex presentation	415	20
Forceps	46	0
Breech presentation	8	0
Face presentation	3	0
Twins	7	1
Total	479	21

There was no maternal mortality. Slight toxic effects were noted in eleven mothers. These included dizziness, a feeling of faintness, giddiness, or numbness, sweating, and slight retching. One mother stated that the injection made her feel 'fighting mad'. These effects were transient.

Of the 508 babies 21 were lost: 8 were stillborn and 8 macerated—a stillbirth rate of 16 (3.2%)—and there were 5 (1%) neonatal deaths, making a total loss of infant life of 4.2%. Of the 8 stillbirths, two followed forceps delivery, two breech delivery, two were found to have atelectasis at necropsy, but both had died *in utero* before pethidine was given. One infant had a bilocular heart and the eighth was a premature twin weighing only 2 lb 6 oz (1.1 kg). Five of the macerated infants died in labour for no apparent cause, and the remaining three consisted of one pair of twins and a premature twin infant. Two of the neonatal deaths were due to gross deformity, one to asphyxia following forceps delivery, one to prematurity, and one to white asphyxia following a very long labour. It was not felt that the administration of pethidine contributed in any way to the infant deaths.

Signs of asphyxia at birth were noted in 55 infants. Of these, 13 were born in a state of white asphyxia or shock, but in all except one there was a definite cause such as operative delivery. Of the rest, the type of asphyxia was not stated in three cases, and in 39 the infant was slightly blue at birth or slow to breathe.

The mean time elapsing between the last dose of pethidine and delivery in the 500 cases was 6.74 hours. It was found, however, that 143 mothers were delivered less than three hours after the last dose, 51 three to four hours after the last dose, and 56 four to five hours after the last dose. In the cases of the mothers of the 55 babies suffering from asphyxia it was found that 13 were delivered less than three hours after the last dose, 4 three to four hours after, and 2 four to five hours after. In view of these findings it seems doubtful if pethidine contributed to foetal asphyxia to any serious extent, though in a few cases it may have caused slight respiratory depression.

The effect of pethidine on the mother in labour was studied in the following ways. Those responsible for the conduct of labour were asked to observe and report the analgesic and amnesic effects of pethidine, and, in addition, patients were asked, either shortly after delivery or on the following day, to express an opinion on the relief of pain and the sedative effect given by the injections. Satisfactory answers were not obtained in all cases, since the memory of labour is often blurred by natural amnesia or by the effect of other analgesics such as nitrous oxide or trilene or by a general anaesthetic given for instrumental delivery. The results are summarized in Tables II, III, and IV under the headings analgesia, amnesia, and patients' opinion.

TABLE II—Analgesic Effect of Pethidine in Labour

Complete analgesia	26
Good analgesia	208
Slight relief of pain	84
No relief	110
Not stated	72
Total	500

Thus out of 428 patients satisfactory analgesia was obtained in 234 (55%). Some analgesia was obtained in 318, or 74% of these 428 cases. In many of the cases in which there was no relief the injection was given much too late in labour—towards the end of the first stage, when it was found that pethidine was often ineffective and that inhalational analgesia as by nitrous oxide and trilene was to be preferred.

TABLE III—*Amnesic Effect of Pethidine in Labour*

Good or complete amnesia	21
Slight amnesia	13
No amnesia	394
Not stated	162
Total	500

Thus out of 338 patients only 34 (10%) obtained any amnesic effect. This confirms the findings by others that pethidine has little such action when given alone. If amnesia is required, some other drug such as hyoscine must be added.

TABLE IV—*Patients' Opinion of Pethidine in Labour*

Very enthusiastic complete relief of all symptoms	30
Good relief of pain	103
Slight relief of pain	18
Slept after injections	126
Able to rest well after injections	96
Able to relax after injections	35
Relieved nervousness	2
Appeared to hasten labour	5
Doubtful	23
No effect	62
Total	500

These results were summed up under the above heading as representing most adequately the statements made by patients when questioned regarding the effects of pethidine. The answers appear to fall into two main groups—those who claimed relief of pain and those who experienced a sedative effect, permitting sleep in many, and in others inducing a feeling of restfulness and relaxation. Out of the 477 patients who gave satisfactory answers, 415 (87%) had had some relief of symptoms following the administration of pethidine. Several patients stated that they found the effect of pethidine of short duration.

The effect of pethidine on the course of labour was studied by noting the action of the injection on the uterine contractions. No effect was noted in 334 cases, or 67%. In 118 (23.3%) the strength of the contractions seemed to be increased and the course of labour hastened, while in 44 (8.8%) the contractions appeared to diminish in strength. No record was available in four cases.

It has been claimed that pethidine reduces the duration of labour, and it was decided to investigate this point by determining the length of labour in this series and in a control series in which no pethidine was given. For control purposes the duration of labour in primigravidae delivered in the Obstetric Hospital, University College Hospital, in the year 1939 was estimated. This year was chosen because 1940 and 1941 were abnormal years, and pethidine has been consistently in use in the hospital since 1942. The results are given in Table V, which shows the mean duration of

TABLE V—*Effect of Pethidine on the Duration of Labour in Primigravidae*

	Total	1st Stage (hrs)		2nd Stage (mins)		3rd Stage (mins)	
		Mean	S D	Mean	S D	Mean	S D
Pethidine	476	29.5	22.0	118.1	117.0	31.2	27.1
Controls	619	22.2	21.2	113.3	90.5	27.0	34.5
Difference		7.3		4.8		4.2	
Standard error of difference		1.3		6.5		1.9	

the first, second, and third stages of labour in 476 out of the 479 primigravidae who received pethidine compared with those in 619 primigravidae delivered in the hospital in 1939.

It will be seen that the patients who received pethidine had a significantly longer first stage than the controls, while there is an apparent prolongation of the second stage which is not significant and is of less than five minutes. The difference in the duration of the third stage is also slight and barely statistically significant. It is fully realized that the pethidine cases were specially selected on account of distress in labour, and form only a portion of the patients delivered in the hospital between 1942 and 1946, so that this is by no means an adequately controlled series. Ideally, of course, for the purpose of such a series, pethidine should be given to alternate primigravidae in labour, but there are many practical difficulties in the way of such an experiment, including the fact that not infrequently patients arrive in the hospital very late in the course of labour and often in the second stage. These results do not, however, support the claims that pethidine reduces the duration of labour.

Forceps delivery was performed in 46 out of the 500 patients who received pethidine in labour. This gives a forceps rate of 9.2%. During the year 1939, 927 patients were delivered in the hospital, 22 by caesarean section. Of the 905 patients delivered per vaginam forceps delivery was performed in 71—a forceps rate of 7.8%. The difference between the two groups is not statistically significant, and in any event the higher proportion of primigravidae in the cases receiving pethidine probably accounts for the slightly higher rate of forceps delivery.

Post-partum haemorrhage—a loss of blood exceeding 20 fl oz (568 ml) after the birth of the baby—was noted in 16 of the 500 cases receiving pethidine. In six cases haemorrhage followed forceps delivery, in one case extraction of the breech was performed under anaesthesia, and there was one case of twins. No cause was apparent in the remaining eight cases. This low incidence suggests that pethidine given in labour does not in any way cause an increased tendency to haemorrhage in the third stage.

As was stated earlier, many of the patients in this series received some other analgesic or sedative in addition to pethidine. It was found that pethidine could be effectively combined with chloral hydrate, 2 fl dr (7 ml) (22 gr (1.5 g) of chloral hydrate) being given by mouth 20 minutes after the injection of pethidine. For the later part of the first stage and for the second stage, nitrous oxide or trilene analgesia was given in many instances. For forceps delivery general anaesthesia was always used.

Pethidine as Premedication for Caesarean Section

Because pethidine appears to produce little or no depression of the foetal respiratory system, even when given shortly before delivery, it has been used for premedication in cases of caesarean section. Records of 37 operations are available for the present series. Pethidine was given in combination with atropine gr 1/100 (0.65 mg), four patients receiving 100 mg, 27 receiving 200 mg, and one, to whom 500 mg of pethidine had previously been given in labour, a total of 600 mg. There was no maternal or foetal mortality. Slight asphyxia was noted in 10 infants, but in eight delivery had been performed under general anaesthesia. In one case epidural analgesia combined with nitrous oxide was used, while delivery in another was accomplished with local analgesia. In this last case there was a slight depression of respiration but recovery was rapid.

General anaesthesia was employed in 17 cases. Epidural analgesia was used alone in six cases and supplemented by nitrous oxide and oxygen in seven. One patient was delivered under local analgesia and one under local analgesia supplemented by cyclopropane. The high proportion

of cases of epidural analgesia is accounted for by the fact that this method was under trial in the hospital while the investigation of pethidine was taking place. Six of the infants were premature, weighing from 3 lb 1 oz (1.4 kg) to 5 lb 8 oz (2.5 kg). In none was there any sign of asphyxia.

This small series is included because it gives evidence regarding the effect of pethidine on the infant. In almost every case the second dose of 100 mg of pethidine was given well within an hour preceding the operation. In only one case could any effect on the foetal respiratory system from pethidine alone be noted, and this was slight and transient. In the cases receiving general anaesthesia it is difficult to assign responsibility for foetal asphyxia. The effect on the mother is not easy to assess, especially as so many received general anaesthesia. The impression was gained that a more useful effect would be obtained by combining pethidine with hyoscine as premedication for caesarean section, though a series of cases would be necessary to prove the safety of this.

Conclusions

Six criteria for the ideal method of relieving pain in labour were laid down by Sturrock (1939). As a result of the experience in 500 cases it is now proposed to attempt to assess how far pethidine fulfils his conditions.

1 "That it does not endanger the life of the mother or child or in any way have an adverse effect upon them"—Pethidine appears to satisfy the first part of this criterion. In the present series there was no maternal mortality. The foetal mortality was low and in no case could foetal death be attributed to pethidine. Toxic effects noted in the mother were slight and transient, amounting to little more than dizziness or a feeling of faintness. It has been stated that pethidine has a slight but definite depressant effect on the foetal respiratory system. In the present series pethidine may have accounted for a few of the cases of slight asphyxia or of slowness in achieving normal respiration. The condition was never severe enough to cause anxiety and recovery was always rapid.

2 "That it abolishes or diminishes pain and the memory of suffering over long periods"—Good analgesia was obtained in the present series in 55% of cases, while 74% of patients obtained some relief of pain. In some of the cases where pethidine failed to procure analgesia it is suggested that the injection may have been given too late in labour. In addition, a definite sedative effect was claimed by a large number of patients, so that 87% experienced relief of symptoms in some form. It does seem possible that there is some personal idiosyncrasy to pethidine. This is noted when pethidine is given in medical, surgical, and gynaecological cases, some patients obtaining marked relief while in others there is little or none. Pethidine has little or no amnesic effect, and if amnesia is required in labour it is suggested that hyoscine be given in addition though it is doubtful whether complete amnesia is either essential or desirable in every labour. Sturrock's second criterion is thus only partly fulfilled by pethidine.

3 "That it does not diminish uterine contractions and thereby delay labour or predispose to atonic post-partum haemorrhage"—In 67% of cases no effect was noted on uterine contractions. In 23% the contractions appeared to increase, and in 8% there seemed to be a slight diminution. The first stage of labour lasted longer in the primigravidae receiving pethidine than in a control series of primigravidae delivered in 1939, but there is a probable fallacy in this observation since the cases receiving pethidine were selected on account of difficulty or distress in labour. No tendency to post-partum haemorrhage was noted.

4 "That during the second stage it does not prevent the patient from co-operating intelligently with the doctor so that an anaesthetic and aseptic technique can be maintained"—This condition is amply fulfilled when pethidine alone is used, as the slight effects of pethidine on the patient do not prevent co-operation.

5 "That there is no necessity for operative delivery solely on account of the method used to alleviate pain"—This condition is also fulfilled, since there was no evidence of an increase in the number of patients requiring forceps delivery after pethidine.

6 "That it is simple to give"—This criterion is easily fulfilled, as a single injection of 100 mg of pethidine appears to suffice for the majority of labours, though some require a second injection and a few three or more. The method of administration, however, presents no practical difficulties.

It may be concluded that pethidine approaches the criteria for an ideal analgesic for use in labour more nearly than any other known substance. Its chief advantages are safety, lack of toxic effects, lack of effect on the course of labour, and simplicity of administration. It may also usefully be combined with other agents. Hyoscine has not been employed in this series, but reports of its use in combination with pethidine are encouraging. It would seem to give the advantage of amnesia, but with the possible disadvantage of lack of co-operation of the patient in the later stages of labour and thus of a possible increased need for instrumental delivery.

It is not suggested that pethidine is necessary in every labour. It is well known that many labours are relatively painless and that much can be done for the patient by encouragement, allaying nervousness, and by the practice of relaxation. These facts are well known and everything must be done to apply them. There are still many cases in which there is real distress. Pethidine helps such patients by allaying suffering and by inducing sleep or restfulness. It is suggested that 100 mg of pethidine be given by injection as soon as the uterine contractions are causing distress. This dose may be repeated in one hour if necessary and thereafter as required. Chloral hydrate given in addition has appeared to enhance the effect. For the later stages of inhalational analgesia in the form of nitrous oxide and air or oxygen or trilete may be used if necessary. This combination will give relief in the majority of cases and is simple and safe.

Summary

The results of the administration of pethidine in labour to 500 patients—479 primigravidae and 21 multiparae—are given.

There was no maternal mortality. Eleven mothers noted slight toxic symptoms.

The foetal mortality was 16 stillbirths (3.2%) and 5 neonatal deaths (1%). Signs of asphyxia were noted in 55 infants, recovery occurred in all. Pethidine may have contributed to slight respiratory depression in a few cases.

Good analgesia was experienced by 55% of mothers. Failures may be accounted for in some cases by the fact that pethidine was given too late in labour. Amnesia was obtained in only 10%. Pethidine given alone does not appear to lead to amnesia.

Some relief of symptoms, chiefly in the form of analgesia or of sleep, and a feeling of restfulness and relaxation were experienced by 87% of the patients.

No effect on uterine contractions was noted in 67%. In 23.3% contractions appeared to increase, while in 8.7% they appeared to diminish.

The duration of labour was compared in primigravidae with a control series of patients delivered in 1939. It was found that the first stage was seven hours longer in patients receiving pethidine. This may be due to other factors, but the claim that pethidine shortens the duration of labour cannot be substantiated.

The forceps rate was 9.2%, comparing favourably with a rate of 7.8% for the year 1939 since the series receiving pethidine contained a high proportion of primigravidae.

No tendency to post-partum haemorrhage was noted.

Pethidine was used for premedication for caesarean section in 32 cases. There was no maternal or foetal mortality.

As a result of this investigation pethidine is compared as an obstetric analgesic with the ideal criteria laid down for such an

agent by Sturrock (1939) Although pethidine does not fulfil all his criteria it is suggested that it approaches the ideal more nearly than any other obstetric analgesic drug in current use

Brief recommendations for the use of pethidine in labour are given

My warmest thanks are due to Prof F J Browne, under whose aegis as Director of the Obstetric Unit at University College Hospital this work was carried out, also to his successor, Prof W C W Nixon, for valuable help with the manuscript

I am indebted to Roche Products, Limited, for supplies of pethidine used in the early part of this investigation My thanks are also due to Miss Monica Cogman for help with the statistical work and to Sister Billing and the staff of the labour wards in the Obstetric Hospital, University College Hospital, whose willing co operation made this investigation possible

The scientists on the whaling factory ship *Balaena* in the Antarctic, have been investigating for the Department of Scientific and Industrial Research methods of ensuring that whale meat is in the freshest possible condition when frozen. There are certain general principles of slaughtering of animals for meat and the handling of carcasses which can be followed only with difficulty in whaling. One of the most important of these is rapid cooling of the carcass immediately after death. Owing to the bulk of the whale's carcass and the thickness of the blubber cooling takes place very slowly, and the meat is therefore likely to go bad rapidly. As the time between death and butchering on the deck of the factory ship may vary considerably, some method of cooling the carcass as soon as possible after death had to be found. An experiment was recently carried out to test a method of doing this. The carcass of a whale when caught is normally inflated with air to prevent its sinking. This causes the whale to roll over on to its back and float belly uppermost. In the experiment portions of the skin and blubber were removed as soon as possible after death to admit cold sea water, which at that time was at a temperature of 30 F (−1°C). It was necessary to insert a special temperature-recording unit deep into the body before this to register the temperature immediately after death and any subsequent change. The leader of the scientific team Dr R A M Case, therefore entered the water as the whale surfaced after its final dive. Clad in a frogman diving suit he swam under the belly of the whale and shot his recording thermometer into it. It was found that when the blubber was stripped from the belly the internal temperature of the whale fell rapidly

AN OUTBREAK OF STAPHYLOCOCCAL FOOD-POISONING

BY

J G ODDY, MB, Ch B

AND

H W CLEGG, MD, DPH

From the Department of Bacteriology and Preventive Medicine
University of Manchester

Since 1930 many outbreaks of food-poisoning have been described in which the evidence has pointed to a staphylococcus as the responsible organism. Commonly, milk and milk products have been the vehicle, but other foods, such as prepared meats, have less often been the medium in which the toxic substance was disseminated. The actual time and place when contamination of the food occurred have been difficult to define, and conclusions have been made on circumstantial evidence. Early last year Williams *et al* (1946) described three outbreaks of staphylococcal food-poisoning due to ice-cream, in two of which, by typing the isolated staphylococci with bacteriophage, they were able to trace the source of contamination to an assistant in the cookhouse where the ice-cream was prepared.

The present article describes an outbreak of staphylococcal food-poisoning due to consumption of pressed pickled beef in which the source of infection was demonstrated by means of bacteriophage typing.

The Outbreak

On Sept 27, 1946, 167 miners at several collieries were taken ill three hours after eating sandwiches containing pressed pickled beef. The outbreak was explosive, and clinically the onset was sudden, with dizziness, nausea, vomiting, diarrhoea, and pain in the abdomen. All the patients were much better in 24 hours and were normal on about three days. Fifteen men were sent to hospital with severe prostration, but were not detained longer than 24 hours.

This outbreak had been preceded by two smaller ones on Aug 16 and 30, involving 16 and 22 men respectively, pressed beef sandwiches being the suspected food. On the first occasion the cause was not established. On the second occasion a staphylococcus was isolated from the pressed pickled beef but not from the vomit. All the meat came from one cooking centre, but in the second outbreak this was not obvious, because the sandwiches had on this occasion been made up elsewhere. Immediately the third outbreak occurred steps were taken to investigate the matter in detail.

The Food—At the centre from which the pressed beef was distributed the meat was cooked, pickled, and pressed by one butcher, who placed it, when ready for cutting, in a large refrigerator of the domestic type, operating at a temperature just above freezing point. The quality of the food and the conditions during preparation were quite satisfactory. The pressed beef was made into sandwiches on the day of distribution to the collieries. One pressed beef sandwich was wrapped in grease-proof paper alone, with another containing either roast beef or corned beef. The whole packet was known as a "B" pack, and stamped on it a date after which the pack should not be eaten (this prevented the sale of stale sandwiches). The "B" packs arrived at the various collieries between 9 a.m. and 1 p.m. on the day of distribution, and were issued to the afternoon shifts at 2 p.m., to the night shifts at 10 p.m. and to the day shifts at 6 o'clock the following morning.

They were eaten about five hours after the miners received them. On the occasion of the outbreak under discussion 1,661 "B" packs were sold among 10,098 miners. The afternoon and night shifts, totalling 1,713 persons, to whom 189 "B" packs were sold, apparently did not suffer any ill effects. All the 167 victims were members of the day shifts, numbering 8,385 men, to whom 1,472 "B" packs were sold. It was not possible to ascertain how many "B" packs each man consumed. Storage conditions varied from colliery to colliery, some having refrigeration, but others having to keep the packs at room temperature—at that time about 74° F (23.3° C).

Bacteriology

Staphylococcus pyogenes aureus was isolated from the vomit of three individual patients by plating, via Robertson's meat medium, and also, by direct plating on blood agar, from a vessel into which several miners had vomited. It was also isolated from some "B" packs remaining at one of the collieries, as well as from "B" packs belonging to the suspected batch that had not been distributed, and was recovered from the outer surface of a block of uncut pressed beef in a refrigerator at the cooking centre. We failed to isolate it from the brine in which the pressed beef was prepared, from the bench on which the sandwiches were cut, and from the bread-slicing machine. Petri dishes of nutrient agar exposed in the centre did not grow a *Staph. pyogenes*.

Kelly and Dack (1936) have shown that staphylococci will grow in meat with a content of 10% sodium chloride, which prohibited the increase of spore-forming and non-spore forming rods, this is in accord with our experience, for after 18 hours incubation the blood-agar plates, after direct plating and plating via Robertson's meat medium, gave a preponderant growth of staphylococci, although a spreading organism finally outgrew the cocci on the plates after three to four days.

A search for carriers was made among the staff at the cooking centre. Swabs were taken from the nose, throat, and any lesions in exposed parts of the body likely to be a source of contamination to the food. In all, 58

TABLE I—*Staph. pyogenes aureus* Found in Swabs from Personnel

No of Persons	No of Swabs	No of Positive Swabs	Site of Positive Swabs		
			Nose	Throat	Hands
25	58	10	6	2	2

TABLE II—Distribution of Positive Swabs

No of Positive Swabs	Total No of People	Nose Only	Throat Only	Nose and Hand	Throat and Hand
10	8	5	1	1	1

swabs were examined from 28 persons, and the results are shown in Table I. The 10 positive swabs came from eight people and the distribution is shown in Table II.

All the coagulase-positive staphylococci from whatever source were of *aureus* type fermented mannite, liquefied gelatin and were haemolytic on horse blood-agar plates. They were all submitted to the central laboratory of the Public Health Laboratory Service for bacteriophage typing. *Staphylococci* belonging to the same bacteriophage type (47-47C) were shown to have been present in the vomit (individual and pooled) B packs pressed beef, and the nose and on the hand of the butcher who prepared the pressed beef. Neither *Staph. pyogenes* nor organisms of the *St. aureus* and dysentery groups were isolated from stool samples submitted from seven patients.

Discussion

An explosive outbreak of gastro-enteritis involving 167 persons two to four hours after they had eaten pressed pickled beef sandwiches suggested the probability of toxic origin. Two independent lines of inquiry led to the source of the trouble. One investigation, by the local and county medical officers of health and their staff, by elimination, led through the common denominator of the pressed beef as a vehicle to the butcher who was the sole person handling the beef in all three outbreaks. In the second outbreak, although the sandwiches had been prepared at another centre, the beef was processed by this butcher. The other line of inquiry, consisting of the chemical and bacteriological analysis of the food and material involved in pickling the beef, showed that inorganic substances capable of toxic effects were absent or were present in normal quantities—for example, nitrites, arsenic, zinc, antimony, lead, mercury, copper, and tin—while *Staph. pyogenes aureus* was isolated from an uncut block of pressed beef and the sandwiches. It had also been isolated from the vomit of individual cases and a communal bucket, as well as from eight of the workers in the food-preparing centre. This evidence was reinforced by bacteriophage typing.

The same bacteriophage type was found in the pressed beef block, the pressed beef sandwiches, the various vomits, and on the person of only one worker in the food-preparing centre—the butcher who was responsible for pickling and cooking the meat and who handled it from the raw state to the finished pressed block ready for slicing. He was harbouring the organism in his throat and in a trivial cut on the palmar surface of his right hand, and it seems most likely that from this second source the contamination of the pressed beef occurred. The cut could easily have been overlooked, and was causing the butcher no discomfort, although the swab revealed a heavy growth of the offending staphylococcus. It was the sort of minor lesion that would have been treated lightly by anyone. The general hygiene of the centre was excellent—floors and benches were clean and the workers wore clean caps and overalls.

It is of great interest that all the cases occurred among the day shifts. The sandwiches were made during the earlier part of the day of distribution, and by the time they were eaten by the afternoon shifts were about eight hours old, by the night shifts 17 hours old, and by the day shifts about 25 hours old. No complaints occurred among the afternoon and night shifts, and it therefore seems that, under conditions prevailing in the sandwiches, it took the organism between 17 and 25 hours to produce enough toxin to cause sickness. Experimental confirmation of this is difficult because the only satisfactory indication of the presence of enterotoxin is the reaction of a human volunteer. The kitten test as described by Dolman and his collaborators (1936) has not been found completely reliable by Fulton (1943). However, under almost identical conditions of temperature and material (five hours' incubation at 37° C, followed by 16 hours' refrigeration and a further six hours' incubation of a pressed pickled beef sandwich) Kelly and Dack (1936), using human volunteers, showed that no ill effects were observed on eating the sandwiches after the first 5 hours' incubation, but that the typical symptoms of staphylococcus enterotoxin poisoning followed the ingestion of the sandwiches at the end of 26 hours. Incidentally they noted that under identical conditions one volunteer showed no ill effects, while another was severely ill. It would appear also that the organisms are capable of producing the enterotoxin under a wide temperature range, because at the collieries storage conditions varied from 35° to 74° F (1.7° to 23.3° C), and yet cases occurred

at each of them and no correlation between the storage temperature and the number of cases could be made out.

The butcher who was the source of the staphylococcus causing the outbreak had local treatment for the lesion in his hand, which soon healed. He also had a course of sulphathiazole, and swabs from his nose, throat, and hand are now negative.

This experience has shown the value and importance in such outbreaks of close liaison between all interested parties and the necessity for thorough and prompt investigation by a bacteriologist with up-to-date services at his disposal.

Summary

An outbreak of toxic food poisoning following the consumption of pressed pickled beef sandwiches is described. The evidence showed *Staph. pyogenes aureus* (phage type 47/47C) to be the cause. Personnel handling food should pay scrupulous attention to personal hygiene and especially to lesions, however slight.

Close liaison between all interested parties was an important factor in finding the cause.

Our thanks are due to Drs Hall, Brothwood, and Carroll and the staff of the Lancashire County Council Public Health Department, especially Mr Eckersley and Mr Ward, for providing many of the circumstantial details. We also wish to thank Prof H B Maitland for his criticism and advice.

Drs Allison and Williams of the P.H.L.S. Central Laboratory at Colindale, kindly phage-typed the staphylococci for us, and Mr C H Walker, analyst to the Lancashire County Council, performed the chemical analyses.

d-TUBOCURARINE IN CAESAREAN SECTION

BY

T CECIL GRAY, MB, ChB, D.A.

Anaesthesia for caesarean section is a subject full of controversy, but the advent of *d*-tubocurarine seems to offer a solution to some of its problems. It assures an easy induction and eliminates any necessity for harmful doses of toxic anaesthetic agents. This report on a series of 30 such operations in which this drug has been used is published in the hope that it will encourage others, who may have greater opportunities in this field of anaesthesia, to explore its possibilities. It is hoped that the constancy in results may convince despite the paucity in numbers.

Technique

The best results were obtained with the following technique and dosages. As premedication, 1/100 gr (0.65 mg) of atropine is given one hour before operation. When the surgeon is scrubbed up and ready, the induction is carried out on the table with an injection of 15 mg of *d*-tubocurarine ("tubarine"—Burroughs Wellcome and Co.) followed by 0.3 g of "kemithal" (cyclohexenyl-allylthiobarbiturate) in 5% solution. Anaesthesia is maintained with cyclopropane, using the closed circuit. The loss of consciousness which results from the initial injection is, however, only transient, and it is necessary that the face-piece of the anaesthetic apparatus be applied without delay. Respiration is "aided" (Gray and Halton, 1946) from the beginning for it is of paramount importance that the small

amount of depression that may result from this dose of *d*-tubocurarine must not be allowed to result in any suboxygenation.

The operation is started as soon as the patient fails to respond to painful stimuli. An early indication as to when this plane has been reached may be afforded by the reaction of the patient to the application of the towel clips. Up to the time of delivery of the child the anaesthesia must be kept as light as possible. It has been found useful to turn the absorption canister out of the circuit for a few minutes before the uterus is incised. In such a short time this has probably little effect upon the mother, but may build up a carbon dioxide tension in the foetal blood which may well contribute to the early commencement of respiration by the baby. After delivery the anaesthesia is deepened as required, but it is not necessary to carry it lower than deep first plane. A pharyngeal airway is not usually inserted. In fact it is inadvisable, as this procedure may well precipitate vomiting. Endotracheal tubes and a laryngoscope are always to hand, but have been found necessary only on the one occasion described later.

Results

There has been a certain dependability about the results of this technique which has been encouraging. There is no anxiety with regard to depression of the infant. With the exception of two understandable cases these babies have all cried most lustily as soon as the head was delivered. They have been quite unusually lively and have shown no evidence of curarization. One of the exceptions was an infant who was rather sleepy but cried after five minutes. In this case thiopentone, 0.15 g, was used for induction instead of the usual "kemithal". The other was a premature baby of 32 weeks weighing 3 lb 2 oz (1.42 kg), and the mother was eclamptic, having had several fits before delivery. This baby took six minutes to expand its lungs.

An increased contractility of the uterine muscle has been observed. The placenta always separates very easily and the uterus contracts down firmly. The injection of "pituitrin" (pituitary lobe extract) which had always been routine was continued in the early cases before this feature was appreciated. It was seen to be unnecessary and has been abandoned. Five patients who it was felt might be predisposed to post-partum haemorrhage received 0.5 ml of pituitrin. The usual indication for this was a justifiable apprehension on the part of the surgeon rather than any unsatisfactory condition of the uterus. Nineteen patients who had no uterine stimulant showed excellent contraction throughout, and not infrequently clots have been observed extruding through the cervix at the end of operation.

As a result of the extremely light anaesthesia the patient wakes up as the dressings are applied, and she often has been told the all-important news before she leaves the theatre. On occasion there have been slight residual signs of curarization at the end of an unusually quick operation, but only twice has it been necessary to inject adequate doses of "prostigmin" and atropine. This has always resulted in complete recovery.

Post-operative vomiting or retching is rare, and is only minimal when it does occur. One of the patients under review developed a chest complication, but it was of doubtful nature and had completely cleared up within 48 hours. There was no evidence of any undue retention of urine, nor have any eye symptoms as reported by Langton Hewitt (1946) been seen. There has been no case of ileus.

Discussion

The ideal anaesthesia for this operation should be safe and, if possible, pleasant. It must provide good working

conditions for the surgeon and be non-depressing to the baby and the uterine tone. The safest technique to date has probably been local analgesia, but there are few who would care to maintain that this is a pleasant experience. Some of these patients who had undergone previous sections have been most grateful for the intravenous induction and the subsequent freedom from unpleasant sequelae.

d-Tubocurarine has passed its experimental stage, and its early promise has been confirmed by further extensive experience. It is debatable whether any potent drug which is delivered into the blood stream can be called safe, but this one seems to be less dangerous than many others in daily use. On the other hand, among these patients were five who were seriously ill: two had eclampsia, having had several fits, two had had extensive haemorrhage from placenta praevia, and one had advanced pulmonary tuberculosis. They all had an uneventful convalescence and with the exception of the last mentioned were fit for discharge within three weeks.

Vomiting during the induction of anaesthesia with consequent aspiration pneumonia is acknowledged to be one of the hazards of this procedure. These patients have not had the usual sedative preparation. They are often admitted as emergencies "off the district," and are not infrequently stout and short-necked. All these factors tend to make the induction period a rather anxious time. The ill advised insertion of an airway immediately after the initial injection did precipitate vomiting in one instance. A cuffed endotracheal tube was inserted, and the fact that suction was ready and to hand prevented any untoward result. Whatever the anaesthetic, these patients are very likely to vomit if they have had a recent meal. A rapid intravenous induction makes the emergency less likely, and the administration of d-tubocurarine undoubtedly facilitates the intubation which may be required as either a prophylactic or a therapeutic measure.

The freedom from curarization of the baby has not been surprising. Whitacre and Fisher (1945) have reported that "intocostrin" (Squibb's biologically standardized extract of curare) has no effect on the infant—an observation which has been confirmed in the present series. Substitution of "kemithal" for thiopentone as an inducing agent and the small amount of anaesthetic which is required after d-tubocurarine are factors which have contributed to the wide-awake condition of these babies.

The good uterine tone that has been so marked a feature was not expected. This has been so striking that on two occasions it caused a temporary embarrassment to the surgeon who found that his hand was being gripped by the contracting uterus as he extracted the child. This has so far not proved a serious handicap, and the otherwise good operating conditions have been ample compensation.

Finally, this technique, by avoiding long post-operative depression which is especially menacing after this operation, undoubtedly contributes to a peaceful and trouble-free convalescence.

Summary

A technique for anaesthetizing patients undergoing caesarean operations using d-tubocurarine, kemithal and cyclopropane is reported. It has been used in 30 cases and the results are reviewed.

My grateful thanks are due to Mr. Percy Malpas and the other members of the chemical team at Whiston County Hospital for their help and confident co-operation.

USE OF d-TUBOCURARINE CHLORIDE AND THIOPENTONE IN ELECTRO-CONVULSION THERAPY

BY

J. A. HOBSON, M.D., D.P.M., B.Sc.

Deputy Physician-in-Charge Woodside Hospital, Honorary
 Chief Assistant in the Department of Psychological Medicine,
 St Mary's Hospital, London

AND

FREDERICK PRESCOTT, M.Sc., Ph.D., M.R.C.P.

Clinical Research Director, Wellcome Research Institution,
 London

Convulsion therapy for the treatment of psychiatric disorders was introduced in 1934 by Meduna, who injected convulsant drugs intravenously. The treatment, however, was so unpleasant that patients were unwilling to continue with it, the considerable rise in blood pressure that occurred rendered it unsuitable for cardiac and arterio-sclerotic patients, and fractures and dislocations were very common. The introduction of electrical convulsion therapy (E.C.T.) (Cerletti and Bini, 1938) diminished the frequency of traumatic complications, but this form of therapy was still unpleasant for the patient, and the rise in blood pressure resulted in cardiovascular accidents which were sometimes fatal. Twenty deaths attributed to E.C.T. have been reported, and 16 of these were either definitely or probably due to cardiac failure (Feldman *et al.*, 1946). By the use of E.C.T. with hyperextension of the spine and mechanical restraint the incidence of compression fractures of the spine has been reduced to about 4% (Cook, 1944), although occasional fractures cannot be prevented. The use of spinal anaesthesia, which has recently been introduced to soften convulsions (Shorvon and Shorvon, 1943), is very limited, as it does not prevent fractures of the arms or jaw, it cannot be used in patients with high or low blood pressure, and it carries with it all the hazards of spinal puncture. Although Bennett (1940) was the first to report on the use of curare for softening convulsions in shock therapy, d-tubocurarine chloride, an alkaloid obtained from crude curare, was used at Woodside Hospital for a considerable time before the publication of this paper. Unfortunately the work was interrupted by the war and was not followed up (Palmer, 1939, 1946). Since 1940 many American workers have confirmed Bennett's observations without, however, modifying his technique.

Curare-like drugs minimize convulsions by paralysing voluntary muscle. They do this by blocking the nerve impulse at the myoneural junction, probably by preventing the effector substance in the muscle from reacting to acetylcholine. In the doses in which it is used clinically d-tubocurarine chloride acts almost exclusively on voluntary muscle and produces few side effects if oxygenation is adequate. A slight fall in blood pressure may occur immediately after its intravenous injection, followed by a slight rise. It has no significant effect on the human electrocardiogram (Gray and Halton, 1946, Prescott *et al.*, 1946). A slight overdose can, however, seriously depress respiration by paralysing the diaphragm, and both bronchospasm and laryngeal spasm have occurred following its use without an anaesthetic (B. G. B. Lucas, personal communication).

Preliminary Investigations

American workers report that combined curare and convulsion therapy is dreaded less by the patient than

convulsion therapy alone, but our experience is directly contrary to this. In our early experiments all patients complained bitterly of the terrifying feeling of suffocation and extreme weakness after an injection of *d*-tubocurarine chloride, and some refused further treatment. We first attempted to relieve the unpleasant symptoms by producing unconsciousness with a preliminary subconvulsive electric shock immediately after the injection of the *d*-tubocurarine chloride. It was found impossible, however, to gauge the dose to such a nicety that unconsciousness with a several-minute amnesia could be produced without the risk of muscular contractions of sufficient strength to cause trauma. It also seemed probable that a preliminary subconvulsive shock raised the electrical convulsion threshold, and it has been reported that subconvulsive shocks cause a serious fall in blood pressure (Silfverskiöld and Amark, 1943) and even cardiac arrest (Kalinowsky and Hoch, 1946). The use of subconvulsive shocks was therefore abandoned.

Preliminary anaesthetization with thiopentone ("pentothal") was found to be a much more satisfactory method of producing amnesia. No patient to whom we have administered thiopentone has remembered anything of either the curarization or the convulsion. Thiopentone has the additional advantages of aiding *d*-tubocurarine in combating the post-convulsive rise in blood pressure, in lessening post-convulsive excitement, and in minimizing the likelihood of bronchospasm which may occasionally follow the injection of curare-like drugs. Contrary to the observations of other workers who have used general anaesthesia with ECT (Neustatter and Freeman, 1939; Fabing, 1942) we have not observed any tendency for thiopentone to increase the electrical convulsion threshold. If anything, the threshold appeared to be lowered, possibly because the thiopentone reduced the patient's excitement and apprehension, which is known to increase the electrical threshold (Kalinowsky and Hoch, 1946). In no case have we failed to induce a convulsion following administration of thiopentone.

Serious respiratory depression resulting from diaphragmatic paralysis is the chief danger of curare-controlled ECT, and unless facilities for controlled respiration are at hand a fatality can occur. There are four deaths reported in the literature from curare-controlled convulsion therapy, two of them most probably from respiratory paralysis (Charlton *et al.*, 1942; Cash and Hoekstra, 1943; Smith *et al.*, 1943; Bennett, 1943). Most of our patients were insufflated with oxygen under slight pressure, by means of an apparatus devised by Dr Lucas, during the period between the administration of the *d*-tubocurarine chloride and the shock, and again following the convulsion if there was the slightest sign of cyanosis or respiratory depression. Unless a large overdose of drug is given the diaphragm recovers its function fairly quickly. In the present series of cases it did not become necessary to administer respiratory stimulants or "prostimin," the pharmacological antagonist of *d*-tubocurarine chloride, ventilation with oxygen being quite adequate to combat any respiratory depression. To counteract the salivation produced by *d*-tubocurarine chloride all patients were given atropine sulphate intravenously in a dose of 1/100 to 1/50 gr (0.65 to 1.3 mg) at the same time as the latter.

Technique

The treatment was usually given in the morning. Patients had their ordinary sedative the previous night. They were allowed a cup of tea at breakfast-time but no food in case of vomiting. Blood pressure, pulse rate, and temperature were taken before treatment. No methods of mechanical

restraint or attempts to hyperextend the spine were used. *d*-Tubocurarine chloride and atropine mixed in the syringe were given intravenously, the syringe disconnected, and without removing the needle from the vein an injection of thiopentone administered immediately afterwards from another syringe. The dose of *d*-tubocurarine chloride required to give adequate relaxation was approximately 2 mg per stone (0.3 mg per kg) of body weight, but this dose has to be varied according to the musculature, age, sex, and general condition of the patient. If the initial injection of *d*-tubocurarine chloride failed to soften the convulsion sufficiently it was increased in subsequent treatments. The lowest effective dose in the present series was 14 mg, and some very muscular male patients were given as much as 30 mg without achieving full curarization. Generally speaking, males require more than females and the young more than the aged. The usual dose of thiopentone was 0.3 g, but this was increased if any tendency to bronchospasm or laryngospasm was noted at the first treatment. This complication was dealt with by anaesthetizing the patient more deeply with a second injection of intravenous thiopentone or with nitrous oxide and oxygen. After the injection of the *d*-tubocurarine chloride an interval of three to five minutes was allowed for curarization to reach its maximum before administering the electrical convulsion. A mouth gag was used only to prevent the possible biting of the lips immediately after the shock. The patient's limbs were not restrained.

Pulse rate and blood-pressure measurements were taken immediately before and after the convulsion, and at intervals of 15 and 30 minutes later. Temperature readings were taken at half-hourly intervals for two hours after the treatment. Many of the patients were insufflated with oxygen following the convulsion, and occasionally, if there was respiratory obstruction, an airway was inserted. Usually the patients passed into a quiet natural sleep after recovering from the convulsion. Out-patients were allowed to sleep for two hours before going home.

The treatment was usually given to patients twice weekly and some who did not respond received short daily courses. One or two patients were given two convulsions in quick succession following a single injection of *d*-tubocurarine chloride and thiopentone. The average number of convulsions given was six, but several patients recovered from symptoms after only two or three. The greatest number of convulsions given to one patient was 20.

Clinical Material

d-Tubocurarine chloride and thiopentone were administered to 50 patients undergoing electrical shock therapy for psychiatric illness, approximately half were in-patients and half out-patients. In all 300 treatments were given. The large majority of the patients were suffering from depression, but a few schizophrenics and obsessional states were included. A careful clinical examination was made before the patient was subjected to convulsion therapy, and if any doubt existed as to the condition of the cardiovascular, respiratory, or skeletal systems, electrocardiographic or radiological investigations were first carried out. An attempt was made to collect as many patients as possible in whom unmodified ECT would have been dangerous if not absolutely contraindicated. Included in the series were hypertensive, arteriosclerotic, and senile patients, patients who had previously sustained fractures in unmodified ECT (one vertebral fracture, and recently wired fracture of the condyloid process of the mandible), a patient who had previously had haematemesis from a peptic ulcer following unmodified ECT, a patient with hernia, and a woman five months pregnant.

Observations

Within three to five minutes of giving the *d*-tubocurarine chloride and thiopentone the patient was relaxed and unconscious, respiration slightly depressed, and breathing mainly abdominal. Immediately after administering the shock the patient gave a slight jerk corresponding to the tonic convulsion, and after a latent period of a few seconds there was a very modified clonic convulsion (see Figs 1 and 2). The arms if they moved at all, were flexed slightly,

FIG 1—Patient undergoing unmodified convulsion therapy showing the stage of clonic convulsion and necessitating lumbar pads and physical restraint by three attendants

FIG 2—Same patient undergoing electrical convulsion therapy after treatment with *d*-tubocurarine chloride and thiopentone. One attendant only is managing the patient and in this case no mouth gag was used

and the fingers were drawn up in the accoucheur position seen in tetany. Usually there was no gross movement of the legs. The cry and opisthotonos of the unmodified convulsion were absent. Although the muscles of the face are those most rapidly paralysed by curare drugs, these muscles contract most strongly in the curare controlled convulsion. The muscles of the eyelids and face twitch repeatedly even when there is no movement of the limbs or trunk so it is always possible to observe that a convulsion is taking place.

Sweating which normally occurs during and after unmodified ECT was usually absent. Slight depression of respiration with a short period of apnoea occurred in most patients but apnoea lasting three minutes is also very common in unmodified ECT (Woolley *et al.* 1942). Slight cyanosis was observed in about a quarter of the treatment given but this was not so frequent, so deep, or so prolonged as that commonly seen in unmodified ECT. Broncho-pneumonia with deep cyanosis which occurred in three very restless patients was relieved by a second injection of thiopentone.

There is normally a considerable rise in blood pressure in the first 15 seconds after an induced unmodified convulsion. It is well above 200 mm Hg (Silfverkröf and Amar, 1943). There is normally an increase of 50 to 60 mm in blood pressure (Kunowsky and Hoch, 1946; Jones and Woolley, 1943). In this series with curare-controlled

convulsions the mean increase in systolic blood pressure was 6 mm Hg (standard error ± 1.7 mm). The diastolic pressure was much the same after the shock as before. It is possible that the rise of blood pressure in uncontrolled convulsions is partly due to the blood being squeezed from the muscles during their violent contractions and shunted into the general circulation, thus increasing the cardiac output and blood pressure. Stimulation of the medullary centres also undoubtedly occurs. It is conceivable that in convulsions modified by *d*-tubocurarine chloride the blood pressure does not rise appreciably because blood is retained in the vessels of the relaxed muscles.

There was often a fall in pulse rate immediately after the convulsion, followed later by a rise. Sometimes there was a fall in body temperature one-half to one hour after the convulsion. The maximum fall of temperature was 2°F (1.1°C), and the lowest temperature recorded was 96°F (35.6°C). This occasional fall was presumably due to the *d*-tubocurarine chloride, as there is usually a slight rise in temperature in the unmodified convulsion. A fall in temperature has also been noted in patients receiving *d*-tubocurarine chloride as an adjunct to anaesthesia (F. Evans, personal communication). It was observed that the effects of curarization passed off about twice as rapidly in a patient submitted to a curare-modified convulsion as in a subject receiving the same dose of drug without a convulsion. The most likely explanation is that electrical stimulation liberates increased amounts of acetylcholine at the neuromuscular junction and that this neutralizes the effect of the *d*-tubocurarine chloride.

Post-convulsive excitement, which is common after unmodified ECT, was rare in the present series, and when it did occur was checked by a second intravenous injection of thiopentone. Many of the patients on regaining consciousness expressed a wish to sit up. Sitting up usually relieves the feeling of suffocation which sometimes persists for twenty minutes or more after the injection of *d*-tubocurarine.

There were no complications such as fractures, dislocations, or muscle strains following any of the treatments and the only unpleasant symptoms between treatments were headache and impairment of memory and concentration, which evidently resulted from the electrical convulsion. *d*-Tubocurarine chloride does not appear to influence the therapeutic effect of ECT or to raise the electrical convulsion threshold. The percentage of patients recovered or markedly improved in the present series is roughly what might have been expected if unmodified ECT had been given, but the number of patients is too small and their diagnoses too varied for any statistically significant conclusion to be drawn.

Discussion

The major drawbacks of ECT—namely fractures, dislocations, and cardiovascular accidents—are largely eliminated by the method described, and post-convulsive excitement is reduced. Preliminary curarization enables ECT to be given to patients to whom unmodified ECT would be dangerous. Mechanical precautions to prevent fractures and dislocations are rendered unnecessary. As no methods of restraint are needed one operator can carry out the treatment single-handed. If the patient should become restless on recovery he can be handled easily as being lightly curarized, he is able to offer only feeble physical resistance.

The dose of both *d*-tubocurarine chloride and thiopentone needs careful assessment. Just enough barbiturate is required to produce about five minutes' narcosis, and sufficient *d*-tubocurarine to make fracture or dislocation impossible but not to depress respiration too deeply. No

patient should be given a curarizing drug unless efficient facilities for controlled respiration with oxygen are at hand and the administrator is competent to deal with the apnoeic patient. The injection of stimulants and analeptics cannot replace the provision of a clear airway and rhythmic insufflation of oxygen using a tightly fitting face-mask. Without the precautions described the treatment advocated might be disastrous, but we feel that with adequate precautions curare-controlled ECT is so much safer than unmodified ECT that we intend to adopt it as a routine procedure. We believe that if patients are curarized with due care the benefits of ECT can be extended to those in whom it would be normally contraindicated. The therapeutic results of convulsion therapy do not depend on the production of a "convulsion," as originally suggested by Meduna (1935), because the end-results are just as good whether the curare modified or the unmodified convulsion technique is used (Bennett, 1941).

Summary

The use of *d* tubocurarine chloride and thiopentone for modifying electrical convulsions is described. In the dosage employed these drugs do not significantly affect the electrical convulsion threshold.

The advantages claimed for the method are: the traumatic complications of ECT are avoided, there is no serious rise in blood pressure, it enables ECT to be given to certain patients in whom otherwise convulsions would be contraindicated, post-convulsive excitement is minimized, the procedure can be carried out single-handed if desired, and the unpleasantness of ECT for the patient is almost entirely eliminated.

Thanks are due to Dr B G B Lucas, of the Surgical Unit, University College Hospital, for the oxygen resuscitation apparatus, which is manufactured by the Medical and Industrial Equipment, Ltd, London.

A registry of primary malignant tumours of bones has been set up with its headquarters at the Department of Pathology, the Royal College of Surgeons of England, with the intention of collecting records of cases of primary tumour or presumed primary tumour of bone (including joints and cartilages) especially those in which cure or prolonged alleviation has been attained by treatment. All cases claimed as five year cures will be considered by the committee, but in future only those cases will be considered in which histological proof of the nature of the tumour can be obtained by biopsy or following amputation. In cases where histological diagnosis is in doubt the Consultant Panel in Morbid Histology set up by the Pathological Society of Great Britain and Ireland in conjunction with the British Empire Cancer Campaign and the National Radium Commission will be consulted. Those interested are invited to send records of relevant cases with amputation or biopsy specimens to Prof R A Willis, M.D., F.R.C.P., Royal College of Surgeons, Lincoln's Inn Fields, London, W.C.2. Donors will be sent reports on the pathological investigation of specimens received, and in return will be asked for follow-up information regarding patients.

USE OF CURARE IN "POOR-RISK" PATIENTS

BY

GORDON OSTLERE, M.B., B.Chir
 Senior Resident Anaesthetist Hill End Hospital
 (St Bartholomew's)

This paper is based on 136 surgical cases in which curarization was performed at Hill End Hospital (St Bartholomew's), and includes the observations of all the members of the anaesthetics department. All of the patients underwent operations of some severity, while most of them were in the "poor-risk" category. An analysis of the operations undertaken in this series is given in Table I.

TABLE I—Operations Recorded

Partial gastrectomy	31	Hysterectomy
Cholecystectomy	7	Thoracoplasty
Resection of large gut	6	Lobectomy
For relief of intestinal obstruction	4	Pneumonectomy
Other laparotomies	11	Ligation of patent ductus
Lumbar ganglionectomy	3	Pericardectomy
Urogenital operations	3	Other thoracotomies
Incisional hernia	2	Oesophagotomy
Resuture of burst abdomen	1	
		Total

Preparations and Dosage

I have used the general name "curare" to embrace all preparations not specifically designated "Intocostarin" (Squibb), *d*-tubocurarine chloride crystals, "curarine" and "tubarine" ampoules (Burroughs Wellcome) have all been employed. The curarine chloride crystals were made up by us in a 1% solution in sterile distilled water or para-chlorocresol which was brought to the boil before bottling. It is impossible adequately to sterilize the crystalline powder in the autoclave. The potency of these preparations remained fairly constant as long as required, in some cases up to six months. An initial dose of 3 ml of Intocostarin or 15 mg of curarine or tubarine was used for abdominal cases, with half the dose usually repeated later for closure of the peritoneum. All injections were made intravenously. The exact calculation of the dose by body weight has the theoretical objection that the number of the patient's myoneural junctions and his weight may not stand in direct relation. The dose was only slightly reduced for children, though very ill and feeble persons, with their slowed metabolism, need less curare and exhibit prolonged effect. Individual reaction to the drug appears to be very variable, but there are too many factors modifying the patient's response to allow of accurate judgment.

All these preparations seemed generally to be reliable, although once Intocostarin and once some curarine chloride made up by us failed to produce the effect expected. Neither of these failures can be attributed to the drug, as subsequent injections from the same bottles produced the usual results. In the latter case the respiration remained adequate, and a considerable amount of ether was given before a lumbar sympathectomy could proceed with tranquillity.

Indications

Limitation of supplies demanded careful selection of cases, curare being used almost exclusively for abdominal and chest operations, particularly with "poor-risk" patients. There would seem to be little point in using curare for procedures where considerable muscular relaxation or very quiet respiration is not called for, as such operations can often be carried out under the narcosis induced as a preliminary to curarization.

Technique for Abdominal Cases

Premedication—The usual premedication for fit adults was omnopon gr 1/3 (22 mg) with scopolamine gr 1/150 (0.43 mg). In some cases mist hyoscin "A" (7 minims, or 0.42 ml, for men, and 5 minims, or 0.3 ml, for women) was substituted. Morphine and atropine in appropriate doses were employed for the young, the old, and the ill, while "seconal" and atropine were given to children.

Induction—Up to 0.5 g of thiopentone (pentothal) was given, and blind intubation performed after the administration of a few breaths of a mixture containing nitrous oxide, oxygen, and carbon dioxide and a small percentage of trilene. Should blind intubation have failed we were prepared to give 15 mg of curarine and perform direct laryngoscopy at once. Thiopentone and curare have been given in rapid succession or mixed, and direct laryngoscopy performed with a Magill laryngoscope, but this was often accompanied by some coughing and straining. We have been chary of giving the curare before the thiopentone, as recommended by Gray and Halton (1946b), in view of the report by Prescott, Rowbotham, and Organe (1946) of the subjective effect of a small dose on the conscious subject. Intubation was performed in every case for the reason put forward by the latter three workers—complete control of the respiration at all times. Endotracheal tubes were lubricated with 5% "nupercaine" in "K-Y" jelly.

Maintenance—Maintenance was by means of nitrous oxide-oxygen and minimal trilene from a semi-closed Boyle apparatus. Ether was used in place of trilene in earlier cases in the series. About 50% oxygen was given to ensure adequate oxygenation, no attempt being made to maintain the anaesthesia by nitrous oxide-oxygen alone. An adjuvant was often needed to prevent movement, and for this purpose a trace of trilene was added to the gases at the beginning of the operation, and for short periods later if required. We have employed this thiopentone-N₂O+O₂-trilene technique without curare for large numbers of orthopaedic, neurosurgical, and similar procedures, with satisfactory maintenance and little post-operative morbidity and discomfort. It is important that only a trace of trilene be employed—not more than at the rate of 1 drachm (3.5 ml) an hour. Should this be insufficient a change-over to another agent should be made, instead of "pushing" the drug (Hewer, 1944). Trilene is preferable to ether as it produces less post-operative vomiting and probably fewer pulmonary complications, while recovery is not delayed and is free from the unpleasant taste and smell associated with ether. It seemed unsound to employ thiopentone as an adjuvant during operation, in view of the possibility of respiratory depression, noticeably lacking with trilene, being added to the respiratory paralysis, as well as the inevitable prolongation of recovery time if thiopentone is employed in any quantity. In cases where ether was used its "curariform" action was noticeable. Curare was given when the peritoneum was first reached, further doses being added as relaxation demanded. With this technique patients invariably left the table with their reflexes fully returned, frequently moving the head and limbs. Mental clarity, with full co-operation, returned rapidly.

Technique for Thoracic Cases

Premedication was the same as that in general cases.

Induction—Up to 0.5 g of thiopentone was followed by cyclopropane-oxygen. Blind intubation was performed under light anaesthesia with a No 7 or 8 Magill tube anointed with 5% nupercaine-K-Y jelly. A Cobb adapter and throat-pack were usually employed. Once the patient had settled down the cyclopropane was turned off. An

intravenous blood drip was then set up. Just before the patient was wheeled into the theatre 15 mg of tubarine or its equivalent was given, administration at this point preventing coughing when the patient was turned on to the table. The insertion of an endotracheal tube was considered essential to provide respiratory control and a perfect airway in an awkward position, and to remove secretions (even in allegedly "dry" thoracoplasties) as soon as they were suspected.

Maintenance—It was often difficult to decide whether to add more cyclopropane to the circuit or another dose of curare to the drip, as it was attempted to maintain the patient with quiet automatic respiration on the one hand and to prevent the possibility of coughing on the other. If the respiration increased in depth 5 mg of tubarine was given, while any movement or an increase in respiration rate (so long as the possibility of anoxia did not arise) was taken as a call for more cyclopropane, 500 ml added to the circuit for one minute usually provided quite enough. We reasoned that the uncured patient under too light anaesthesia would respond to stimuli by coughing and by an increase in the depth and rate of respiration. As the first two responses were abolished by curare the last of the triad would indicate lightening anaesthesia. In view of the unstable pulse rate produced by cyclopropane and intrathoracic manœuvres, this was ignored as a sign of inadequate narcosis. Gray and Halton (1946b) report this sign particularly under barbiturate narcosis. Arrhythmias were, however, strikingly uncommon with this technique. It must be confessed that the signs of depth of anaesthesia and curarization were most difficult to evaluate. Tracheal tug occurred quite commonly, and was abolished by further curare. Aided respiration was frequently employed as needed.

About 15 to 20 mg of tubarine was required for a first-stage thoracoplasty, and about 20 to 30 mg for a lobectomy or pneumonectomy. More was needed for operations performed under controlled respiration, such as repair of diaphragmatic hernia. The results in chest cases were most striking. The blood pressure remained steady, even in severely ill patients, for much longer than in those operated on under cyclopropane alone, all the patients becoming alert, co-operative, and moving almost as soon as they were returned to bed. The temperature returned to normal within one to two hours, and the pulse and blood pressure rapidly recovered from any deterioration. Moreover, the patients felt much better after operation than uncured patients undergoing similar procedures. Curare seems to be of maximum benefit to the unfit subject needing thoracic surgery.

Treatment of Laryngeal Spasm

Tubarine 10 mg was given intravenously to two patients who developed severe laryngeal spasm during induction producing almost instantaneous relaxation of the adductors of the cords with the restoration of a clear airway. This use of curare has been reported by Organe (1946).

Complications

Ocular Complications (Table II)—Twenty cases with eye trouble after the use of curare have been seen. In most instances the complaint about the eyes was volunteered, otherwise the patient was subjected to the most

TABLE II—Ocular Complications

No of Cases	Duration of Symptoms		Diplopia	Blurring of Vision	Pain	Ptosis	Spots
	Up to 24 hrs	Over 24 hrs					
20	9	11	5	13	5	2	2

guarded questioning Blurring of vision was the commonest fault complained of, often accompanied by one or two other defects In more than half the cases the symptoms persisted for over 24 hours, but never longer than three to four days, all of them began with the return of consciousness One patient showed a "myasthenia gravis effect, in which ptosis occurred and accommodation failed after reading for a short while, to return to full efficiency after a rest In another case prostigmin, administered for retention of urine following hysterectomy, immediately cured an incidental blurring of vision A further patient, who was given curare for the first and second stages of a thoracoplasty, developed blurring of vision on both occasions The analogy between the pathology of myasthenia gravis and the pharmacology of curare is, however, not a true one In myasthenia no impairment of pupillary function occurs (Walsbe, 1943) Nothing abnormal was found on examination of the eyes Apparently similar ocular complications did not occur after ordinary general anaesthesia, as none of the patients volunteered information to this effect So far as can be gathered from such a small series, the anaesthetic agent has no effect on the subsequent complications

These phenomena may be due to a "hang-over" action of the curare The muscles concerned are unique in being suddenly put to full use almost immediately consciousness returns and in producing through slight defects, an effect easily apparent to the patient This was particularly the case in the presence of a pre-existing compensated slight fault One is tempted to surmise that all the muscles of the body may suffer in some degree from the effects of curare for some time after operation

Amnesia—One case anaesthetized with thiopentone 0.5 g, N₂O-oxygen, and trilene, with 15 mg of tubarine, developed prolonged drowsiness and amnesia for the 24 hours following operation, although this is more likely to have been due to the thiopentone than to the curare Similar cases have been reported by Landau and Wooley (1934)

Effect on Blood Pressure

There seems no doubt that increased bleeding occurs after curarization and that the blood pressure very commonly rises a matter of 10 to 20 mm, while in one case a rise from 125/90 to 200/130 mm was recorded in 35 minutes This consideration has led to a refusal to administer curare for electro-convulsive therapy in a patient with hypertension The blood pressure has been seen to fall as surgical stimuli became severe, to rise again as they cease, exemplifying the retention of vasomotor control under light anaesthesia mentioned by Gray and Halton after quoting the work of Zweifach *et al.* (1945) Some cases showed no drop in blood pressure however severe the stimulus In others the blood pressure seemed to fall as the curare wore off, to be restored by a further injection, although complete relaxation was present

Post-operative Results (see Table III)

It must be emphasized that not only was curare employed for many operations most likely to be followed by thoracic complications, but as supplies were short the

drug was purposely reserved for patients who were considered to be "bad risks" It should further be mentioned that, to give curare as strict a trial as possible, very severe criteria of "chests" and vomiting were applied Any vomit at all was classed as "slight" vomiting, and any cough with sputum a "minor" chest In a small series it is impressions that count, not statistics Our impression was that, though curare proved an inestimable boon in the theatre, it had no effect on the frequency of post-anaesthetic vomiting in comparable operations, and possibly slightly reduced the incidence of anticipated chest complications The patients recovered consciousness much sooner and recovery was more pleasant—not inconsiderable advantages, otherwise there was no difference post-operatively whether curare was given or not The greatest advantage of curare is that it enables very ill patients—particularly those needing thoracic surgery—to undergo operation without a dangerously prolonged deep anaesthesia and to recover rapidly from the immediate effects of the operation

Deaths following Curare

Eight patients died some time after receiving curare All of them were in poor physical condition before operation, and they represent a high proportion of the total surgical mortality in the hospital for the period One patient died of peritonitis five days after a subtotal gastrectomy The others succumbed to heart failure, in two cases accompanied by bronchopneumonia and in one case by acute dilatation of the stomach One patient suffered two coronary thromboses twelve hours after a cholecystectomy, two had extensive carcinoma of the stomach, and two more were severely ill with intestinal obstruction Another was undergoing lobectomy for multiple abscesses in the middle lobe of the right lung A further patient developed Stokes-Adams attacks after an exploratory laparotomy (for which curare was used), and died of one of these attacks after a second curarization for resuture of a burst abdomen One patient died in the theatre, and the others at periods between four hours and fourteen days after operation

Necropsy in the last seven fatal cases confirmed the cause of death as heart failure and demonstrated a fat flabby heart with coronary sclerosis of varying severity one case had in addition bilateral obliterative pleural adhesions Only one patient showed respiratory depression requiring controlled respiration in the theatre, and in no case was anoxia allowed to occur Although curare cannot be implicated in any of these cases, in which death would probably have occurred whatever form of anaesthesia was used, it is worth noting that the two fatal cases in Gray and Halton's (1946a) original series present a similar picture There is still the possibility that further investigation of the pharmacology of curare may reveal some action upon the heart

Summary

Observations are recorded on 136 cases in which curare was administered, mainly for severe operations in patients of the "poor risk" type

TABLE III—Post-operative Results

Agent	Chest Complications				Vomiting			Ocular Complications	Ileus and Acute Dilatation of Stomach
	Major	Minor	Aggravated	Total	Little	Much	Total		
Nitrous oxide-oxygen-trilene (69 cases)	5.8	10.2	7.3	23.3	23.2	2.9	26.1	14.5	1.5
Nitrous oxide-oxygen-ether (28 cases)	—	25.0	10.7	35.7	42.8	7.4	50.2	17.9	3.7
Oxygen-cyclopropane (39 cases)	—	—	17.9	17.9	33.3	15.4	48.7	12.8	—
Total	2.9	10.3	11.0	24.2	30.1	7.3	37.4	14.7	1.5

The efficacy and dosage of curare preparations are considered, and techniques employing trichloroethylene for abdominal cases and cyclopropane for thoracic cases described.

Twenty cases with ocular complications are reported. The effect of curare on the blood pressure and on severe laryngeal spasm is also mentioned.

An analysis of post operative results is given and eight deaths after curarization are discussed.

My thanks are due to Dr C Langton Hewer for his kind permission to publish this paper, and to both Dr Hewer and Mr B Rait-Smith for their ready and valued encouragement and advice also to my colleagues for their observation and help.

d-TUBOCURARINE CHLORIDE IN ELECTRO-CONVULSION THERAPY

BY

A GILLIS, MB, BS, BSc

AND

D D WEBSTER, MB, BS

It is now generally known that *d*-tubocurarine chloride is used to obtain good relaxation in general anaesthesia. Its value as an aid in electro-convulsion therapy may, however, be of equal importance. Griffith (1946) reviews the history and present knowledge of the clinical use of *d*-tubocurarine chloride, with special reference to anaesthesiology, and discusses the physiological action of the drug. A further review of the literature is given by Kellgren *et al* (1946).

An obstacle to the use of electro convulsion therapy in feeble persons has been the strain imposed on the skeletal structure by the violent muscular contractions produced. *d*-Tubocurarine chloride enables electro-convulsion therapy to be given in cases in which the physical condition would otherwise be a contraindication.

Methods—The drug is given intravenously, and in our experience it is advisable to test the patient's tolerance with small doses before electro convulsion therapy. We commence with 1 mg per stone (6.4 kg) of body weight, and this is increased on successive days until the patient is just unable to raise the head from the pillow after about four to five minutes. Electro-convulsion therapy is then given in the usual way.

One of our cases was a woman who in attempting suicide had sustained a fractured surgical neck of the humerus and a fractured pelvis. She was in a state of acute melancholia and actively suicidal. Electro-convulsion therapy was required, but the recent bone injuries made its administration impracticable. Under the influence of 15 mg of *d*-tubocurarine chloride the electroplexy produced a mere 'purring sensation' in the muscles. This procedure was repeated on six occasions and she made a good psychiatric recovery, and she was up and about, with a good orthopaedic result, when she left hospital.

Another illustrative case was that of a reactive depression in a man of 34 who complained of severe pain in his back after one dose of electro-convulsion therapy. X-ray examination showed no bony injury of the vertebrae, but in the ordinary way treatment would have been discontinued. With *d*-tubocurarine chloride it was possible to continue treatment. His pain has now gone and he has made a social recovery. This was one of our early cases, and an initial dose of 20 mg was given. There was marked respiratory paralysis and apparent loss of consciousness. The pulse remained of good volume and regularity throughout, and after about five minutes' artificial respiration normal respiratory rhythm recommenced. An interesting feature was that the patient was later able to give an account of the artificial respiration and other restorative measures (physostigmine, etc.), taken during a period when he appeared to be deeply unconscious. It seems then that the drug despite its dramatic effect on motor activity, had little influence on the sensorium. This is in agreement with the findings of Kellgren *et al* (1946).

Conclusion—*d*-tubocurarine chloride appears to be effective in minimizing convulsions in electro-convulsion therapy. Although both *d*-tubocurarine chloride and electro-convulsion therapy are respiratory depressants no synergistic action between the two has been noted with the relatively low dosage used.

We wish to thank Dr F Back, Medical Superintendent, Cherry Knowle (Sunderland Mental Hospital), for providing the facilities for this work.

Medical Memoranda

Unusual Case of Poisoning by Zinc Sulphate

The following case seems worth recording because of the unusual sequelae. In the literature at my disposal I cannot find any description of a similar sequence of clinical events.

CASE HISTORY

An Indian woman aged 35 was admitted into the General Hospital, Johore Bahru, Malaya, at 9.30 a.m. on March 4, 1946. About one and a half hours previously she had taken a dose of 'salts' for constipation, and this was followed in a few minutes by vomiting and purging. The substance swallowed was mistaken for Epsom salt, and approximately 1 oz (28 g) was taken. The bottle with the remaining noxious contents was brought to hospital, and the white crystals proved on analysis to be zinc sulphate. The vomitus contained the same substance.

On admission the patient was acutely collapsed and very restless. There was no abnormality of the lips, tongue or buccal mucosa. Treatment with demulcents, morphine, and nikethamide produced marked improvement within twelve hours. On March 5 her general condition was satisfactory, and vomiting had ceased. There had been no haematemesis. She complained of abdominal pain of a colicky nature, but examination revealed no abnormality. The temperature was normal, there was a persistent tachycardia of 90 to 100 a minute, and examination of her urine showed no abnormality, chemically or microscopically. On the 6th progress was well maintained and there was no blood in the stool. Next day the improvement continued, but she vomited two *Ascaris lumbricoides*. At about 8.30 a.m. on the 8th I was informed that the patient had suddenly collapsed. On examination she was found to be semi-comatose with a marked ketosis. Blood was sent for estimation of the sugar content, and a catheter specimen of urine for examination. Insulin therapy was immediately instituted 60 units of the soluble product, of doubtful potency, being given intramuscularly, as the intravenous route was impossible owing to collapse. Nevertheless, the patient's condition continued to deteriorate and she died at 7.30 p.m. The blood sugar was 380 mg per 100 ml, and the urine was loaded with albumin, sugar, and ketones.

Necropsy was performed at 2.30 p.m. on March 9 the report was as follows. The body was that of a fat woman of average build. Rigor mortis was absent. The peritoneal cavity contained about 4 oz (114 ml) of blood stained fluid, there was no evidence of fat necrosis. Liver size normal, rather fatty. Gall bladder size normal, contained six faceted pigment stones. Spleen normal. Kidneys both intensely congested and haemorrhagic. Suprarenals congested. Pancreas size normal, generally congested, the tail was very intensely haemorrhagic. Stomach very congested, mucous membrane eroded and, in places, desquamated, no perforation. Bowel congested only, no perforation. Bladder normal contained about 2 oz (57 ml) of turbid urine which, on examination, showed copious albumin, sugar, ketones and blood—microscopically there were numerous erythrocytes and epithelial cells. Pleural cavities normal. Lungs normal. Pericardial sac normal. Heart somewhat flabby, otherwise normal. Samples of pancreas, kidney, liver, and suprarenals could not be examined histologically, as facilities did not exist.

COMMENTARY

This seems to be a clear case of poisoning by zinc sulphate. Treatment of the original collapse was successful, and progress was well maintained until the fifth day, when hyperglycaemic coma developed. Unfortunately the circumstances precluded daily examination of the urine, otherwise pancreatic insufficiency and renal damage might have been noted earlier. Nevertheless, twelve hours before the onset of coma no premonitory symptoms or clinical signs of hyperglycaemia were observed. It is regrettable that histological examination of the tissues mentioned could not be carried out, but in view of the gross pathological findings at necropsy I feel that this case should be regarded as one of haemorrhagic pancreatitis and widespread renal damage as a result of poisoning by zinc sulphate, with hyperglycaemic coma and death supervening on the fifth day.

My thanks are due to Major S. N. Mittra I.A.M.C. who carried out the post mortem examination.

GEORGE A. B. COWAN M.B., Ch.B.,
Malayan Medical Service

Post-partum Intra-abdominal Separation of Uterus

The following report of what must be a very rare condition may be of interest.

CASE HISTORY

On March 28, 1946, at 10 a.m., a primiparous European woman of medium build, 25 years of age, spontaneously gave birth to a male child of 8 lb (3.6 kg), after having been in labour for 8½ hours, a nurse only attending to her at home. No difficulties were experienced during this stage of the confinement, the placenta, however, appeared to be adherent, and all attempts by the nurse to expel it proved fruitless. It is stated that the patient had some diffuse haemorrhage, but no clots were passed. At 12.30 p.m. (2½ hours after being confined) the doctor was called, and he is alleged to have given her three injections: first 0.5 ml ergometrine subcutaneously, then 10 ml calcium gluconate intravenously, and half an hour afterwards a second 0.5 ml ergometrine subcutaneously. The patient claimed that the doctor did not attempt to expel the placenta, nor did he examine her abdomen or make any other examination. Her condition continued to deteriorate and she was admitted to the Germiston Hospital at 5 p.m. (seven hours after confinement). On admission she was in a state of collapse, with a feeble pulse and a blood pressure of 60/20 mm Hg. She was very anaemic and somewhat restless and there was a slight continuous ooze of bright red blood. The uterus was in a state of contraction. Pressure on the abdomen was resented. A blood transfusion of 1,000 ml of whole blood was given followed by 1,000 ml of serum.

Operation.—At 11 p.m. the patient's condition was considered sufficiently improved to attempt a manual removal of the placenta, and the operation was performed by a house surgeon, with the patient under a general anaesthetic. After having worked for twenty-five minutes he discovered omentum at the vulva. At this stage a further 1,000 ml of whole blood was being transfused, although there was no excessive haemorrhage during the operation. I was then called into consultation, and was able to open the abdomen twenty minutes after the discovery of omentum in the introitus. To my surprise I found the uterus completely severed, not a tag connecting uterus and host remained. Apart from a fair amount of blood in the abdominal cavity only three relatively

small bleeding points were found—one on either side in the four ligaments of the ovaries, and a third in the right uterine fold—were clamped and ligatured. The uterine arteries could not be seen nor was there any retroperitoneal haemorrhage. The stretch of cervix was torn through and severed from the body of the uterus, with a fair sized flap of peritoneum anteriorly. The broad bands with round ligaments of uterus and ovaries presented a continuous flap on either side. The Fallopian tubes, however, were torn off separately. Both ovaries were intact. There was no damage found on any of the adjoining viscera or ureters. With some reluctance it was decided not to look for the uterine arteries as there was no sign of haemorrhage from them. The condition of the patient was somewhat precarious, and ligating these arteries would also have involved

Photograph of the uterus, showing the protruding umbilical cord and placenta, and the attached pieces of the uterine arteries.

ligating a major branch of the internal iliac artery. Very little trimming of the cervix stump was necessary. It was stitched, peritonealized, and the wound closed. The operation lasted about thirty minutes.

Her recovery was uneventful. She received penicillin (20,000 units three hourly) and sulphadiazine (2 tablets four hourly) with mist pot cit for the first four post-operative days. During these four days she had to be catheterized, after which she passed urine spontaneously. On the third post-operative day her blood pressure was 130/80 mm Hg, and her temperature, which showed a slight elevation (102° F, 38.9° C) settled to normal on the fourth day. She was discharged from hospital on the seventeenth day. On April 29 (one month after operation), when I last examined her, she enjoyed excellent health, and was apparently no worse for the loss of her uterus.

The specimen consisted of a contracted uterus with the placenta *in situ*, a few inches of umbilical cord and a bit of placenta protruding. On examination the placenta did not appear to be adherent. The circular tear went through the stretched cervix near the body of the uterus. Anteriorly the specimen was largely stripped from its peritoneum, while posteriorly the serosa was left intact. Both sides of the specimen showed tags of ligamentous tissue derived from the round ligaments of uterus and ovaries. Small ends of the Fallopian tubes were also left intact. Long pieces of the uterine arteries were attached to the specimen 3½ in (8.9 cm) on the right side and 2½ in (7 cm) on the left side, apparently torn off at their origins from the internal iliac arteries (see Fig.).

COMMENT

This patient made a definite statement that prior to 11 p.m. on the day of her confinement she had not had an anaesthetic nor had she been examined per vaginam either by the nurse or by the doctor, yet there had been diffuse bleeding to account for her collapsed condition. The ergometrine injected at 12.30 p.m. and 1 p.m. respectively apparently accounted for the contracted state of the uterus. One may ask, Was there a uterine tear prior to the house surgeon's operation, and, if so, how had it happened? Is it possible to cause a uterine tear by exercising abdominal pressure, or by Credé's method of expelling the placenta? Whatever the answer may be, the patient's survival after such a gross lesion must be without parallel.

Reviews

INTRODUCTION TO PHYSIOLOGY

The Physiology of Tissues and Organs (An Introduction to the Study of Systematic Physiology) By Douglas H K Lee, M.D., F.R.A.C.P. Professor of Physiology, University of Queensland (Pp 159, illustrated No price given) Brisbane University of Queensland 1946

This little book is most entertaining, and we should like to see it made available in this country. Although it is intended for the use of the author's own classes, it would be potentially thought provoking to any student beginning the study of physiology. Indeed it would be of value to any teacher of the subject, too, and to students already well on the way.

We have seen no other book at all like it. The main line of approach is by way of general biology and general physiology. The systems are dealt with in a general way, and then some examples of integration of function and of practical applications of physiological knowledge are discussed. There is little reference to the biochemical aspect of the subject, the reason given by the author being that it is treated as a separate discipline (The physiologist might ask what this "special discipline" of biochemistry is.) The author, however, is careful to point out that what his teachers have put asunder the student must try to join together, so that the knowledge "possessed by the student when he leaves the department should be a unified knowledge." This is not a criticism of the book, the author is in the same difficulty as most other physiologists in these days when people talk of unity but act as separate units—presenting, perhaps a picture of unity in diversity. Prof Lee's book is refreshingly original, and we congratulate the author on the production of a useful guide.

C LOVATT EVANS

SURFACE ANATOMY

Surface and Radiological Anatomy for Students and General Practitioners By A B Appleton M.D. W J Hamilton, M.D. FRSEd, and G Simon, M.D., BCh, DMRE. Second edition rewritten (Pp 332, 390 figures 31s 6d) Cambridge W Heffer and Sons

This standard work is a valuable guide to the examination of the living subject by methodical observation, palpation, and skiagraphy. The authors have introduced new skiagrams and illustrations into this edition, and substantially improved the text. The difficulty often experienced by beginners in interpreting certain skiagrams and the appearances seen in fluoroscopy will be reduced by studying the reproductions of normal skiagrams taken from the anterior, posterior, and oblique viewpoints and showing distinctly certain landmarks whose location when understood, gives the key to the whole picture. Moreover, the authors explain their technique lucidly and in sufficient detail to reveal the principles underlying kymography and tomography as well as more ordinary radiological methods. The use of contrast media in the examination of hollow organs and tubes is also admirably described and illustrated. Many skiagrams are shown beside drawings of the corresponding parts—for example heart and large blood vessels exposed by removal of the overlying structures—an arrangement which facilitates the interpretation of certain details in the ray pictures.

Special features of the book are the skiagrams and descriptions of the skeleton, including the centres of ossification and epiphyseal disks, the illustrations of the joints in various positions of the limbs, the grouping of the muscles according to their functions, the clear representation of the motor points as seen in relation to muscular elevations of the overlying skin in a well-developed subject and the accounts of segmental distribution of the nerves with tables, and of the radiological examination of the thoracic abdomino pelvic and cerebrospinal regions. The reader studying the book and verifying each point by examination of a living subject will attain in a relatively short time knowledge that the authors have spent many years

in gathering. All concerned are to be congratulated on having produced a work that will serve both as a textbook in the initial stages of anatomical study and as a reliable book of reference for practitioners.

NURSING IN INDUSTRY

Nursing in Commerce and Industry By Bethel J McGrath, R.N. For the National Organization for Public Health Nursing (Pp 356 53 00 or 16s 6d) New York The Commonwealth Fund London Oxford University Press 1946

The author of this book was formerly the industrial nursing consultant of the National Organization for Public Health Nursing and with the sponsorship of this organization she undertook to prepare a comprehensive guide to the manifold duties of the industrial nurse. A few of the more technical portions of her subject are the work of other hands. Dr Alice Hamilton points out in an introduction that the book is not only for nurses but for the general public as well.

It is stated that the earliest record of a nurse being employed in an industrial concern in the U.S.A. was in 1895. Progress was very slow at first, and it needed the stimulus of the two world wars to establish adequate nursing services. By 1918 some 1,200 nurses were employed in industry, and in 1927 there were 2,200. By 1941 the number had risen to over 6,000, and by 1943 to nearly 13,000. The relationship of the nurse to the industrial organization under which she is to work and her duties and responsibilities are fully described. In an interesting chapter on mental hygiene some of the types of people specially needing help are discussed. They include the fault-finder, the misfit and those suffering from hysteria, money troubles and family difficulties. In the chapter on control of communicable disease, respiratory diseases and especially tuberculosis are dealt with at length. The book can be cordially recommended as an up-to-date account of nursing services in the U.S.A., but it makes no reference to experiences in Great Britain.

H M VERNON

BACTERIOLOGY FOR STUDENTS

A Textbook of Bacteriology By R W Fairbrother, M.D. DSC FRCP. Fifth edition (Pp 480 illustrated 17s 6d) London William Heinemann Medical Books 1946

This popular book, now in its fifth edition, is admirably suited to the medical student's needs. The author emphasizes the theoretical aspect of the subject and its important applications in medicine, omitting technical detail which is either superfluous or better learnt at the bench. There are a few new illustrations—the inclusion of more would improve the book, and the coloured plate of tubercle bacilli, some of which are shown unnaturally curved, might be redrawn. Chemotherapy and its laboratory uses are now discussed in a separate chapter and are referred to also in connexion with each susceptible micro-organism.

L P GARROD

BIOCHEMISTRY ON THE CONTINENT

Exposés Annuels de Biochimie Médicale Published under the direction of Michel Polonovski. Sixth edition (Pp 301 580 francs) Paris Masson et Cie

This issue of the French annual review of medical biochemistry will be welcomed by many readers in this country, for during the war Continental literature was not easily accessible here and the book contains many articles which discuss work done in France and other European countries during those years. For instance, there is an article by Polonovski and Busnel on the biochemistry of pterines, a group of substances which have recently become interesting in view of their relation to folic acid, fully reporting the work of Wieland and his school on their chemical constitution and synthesis. Data are given on the distribution of pterines in the animal kingdom and their possible functions in metabolism are discussed. Sannicciulli contributes an article on pigments and antibiotics of bacteria and fungi. Roche reviews the work on enzymes which contain a

dissociable metal—a group characterized by an easily ionizable metal constituent which can be removed and, in some cases, replaced by another similar metal. In the iron-containing enzymes—e.g., peroxidase and catalase—the metal is firmly built into a ‘prosthetic group’ of the same type as the haem in of red blood pigment, but there are many enzymes where the metal ion has the character of a coenzyme which can easily be removed by dialysis. In some cases the metal becomes dissociable only after treatment of the enzyme, and other enzymes can be reactivated by metal only when special organic coactivators are added.

Fromageot discusses certain aspects of sulphur metabolism, especially the experimental work on the formation of cystine from methionine and on the oxidation of the sulphur contained in the amino acids cysteine, cystine, and methionine to inorganic sulphate. He suggests that the first step is the removal of the organically bound sulphur from cysteine and homocysteine as hydrogen sulphide, which is subsequently oxidized to sulphate. This suggestion is supported by experimental evidence published in France during the war. Roskam discusses experiments of his own and his colleagues on the effect of sympathetomimetic substances on the bleeding time. The chief outcome of his work is the observation that adrenochrome, an oxidation product of adrenaline without sympathetomimetic action, is as effective as adrenaline itself in reducing the bleeding time. Adrenochrome acts with a shorter latent period than adrenaline, and this is interpreted as indicating that adrenaline acts after being converted into adrenochrome.

The volume also contains a review by Boulanger on the role of sodium and potassium in the animal body and a short discussion by Corbier on functional correlations among steroids. A clearly written and useful article on spectrographic methods in biology is the posthumously published work of G. Florence, who lost his life in 1945 in German captivity.

ASPECTS OF PSYCHIATRY

Modern Attitudes in Psychiatry The March of Time, 1945 (Pp 154 13s 6d) New York Columbia University Press London Oxford University Press 1946

The New York Academy of Medicine sponsors certain lectures to the laity. The subject decided upon for 1945 was the use of psychiatry in medicine, and the present volume contains reprints of lectures by six distinguished American psychiatrists. In these the modern attitude is admirably set out for the intelligent layman. After a foreword by Dr Rhoads, the acting president of the Academy, and an introduction by Dr Zabriske, Dr Goldston opens the series with a historical survey of psychiatry in which he points out that psychological medicine began with Hippocrates and that ancient and mediaeval treatment was indeed really more ‘psychic’ than somatic. Dr Wall deals in greater detail with the history of the subject since the days of Pinel. Then follows an admirable essay on the social aspects of medicine in which it is shown how illness, even if it is organic, can be modified by emotional stresses and strains, and how the patient can be properly treated only if his whole personality, mind, body, and environment are taken into account. In the fourth lecture Dr Alexander discusses the future outlook for psychiatry from the psycho-analytic standpoint, but he stresses the need for shorter forms of treatment.

Col Menninger describes the psychiatric arrangements in the Services and the advances in preventive diagnosis and treatment achieved, with the lessons for peacetime practice. Finally Dr Weiss, discussing the role of the general physician in psychotherapy, points out that much ‘minor’ psychotherapy can be carried out without specialist knowledge, though ‘major’ psychotherapy must remain the province of the specialist. One of the worst features in the history of medicine according to Garrison and Allbutt was the divorce of medicine from surgery. As Dr Weiss suggests, an even more unhappy separation may have been the divorce of both from psychiatry.

These lectures are well worth perusal both for their own merits and because they illustrate how even difficult medical problems can usefully be brought before the lay public in an understandable form.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Brompton Hospital Reports Vol XIV 1945 (Pp 175 10s) Aldershot Research Department of the Hospital 1947

Includes articles on pleural and pulmonary suppuration treated with penicillin, prognosis of successful pneumonectomy, pulmonary hydatid disease, surgical treatment of carcinoma of the oesophagus and a review of pulmonary tuberculosis.

Problems of Malnutrition and Starvation During the War By Sir Jack Drummond DSc, FRIC, FRS (Pp 21 1s 6d) Nottingham University College 1947

A reprint of the author's Sir Jesse Boots foundation lecture, 1946.

Diseases of Children Edited by D Paterson, MD, FRCP and A Moncrieff, MD, FRCP Fourth edition Vol I (Pp 771 30s) London Edward Arnold 1947

This well known book includes new material on the surgery of congenital deformities, sulphonamides and penicillin for infants, acid base regulation, anaesthetics for children, abdominal pain, pneumonia, and collapse of lung.

Poisons By V J Brookes and H N Alyea (Pp 209 16s 6d) New York D Van Nostrand 1947

A summary of the properties of poisons, and the symptoms and treatments of poisoning.

In Amintrea Profesorului Fr J Rainer (Pp 123)

L'Oeuvre Scientifique de Fr J Rainer—Vol I Neurologie Végétative (Pp 57) Vol II Structure Fonctionnelle (Pp 154) Vol III Anthropologie, Morphologie (Varia), Bibliographie (Pp 121)

Le Métopisme Chez les Roumains et en Général By Fr J Rainer and Al Tudor (Pp 35) Bucharest Impremaria Nationala 1946

The first of these is a memorial volume to Prof Rainer, of Bucharest, who died in 1944, in Rumanian. The other books are collections of papers by Prof Rainer, some written in collaboration with other authors, illustrated, in French.

Les Etats Psychopathiques Infantiles d'Origine Syphilitique Héritaire Larvée By Henry Brantmay (Pp 73 No price) Geneva Georg 1946

A monograph on the aetiology and symptomatology of congenital syphilis, in French.

Legislacion sobre Seguridad e Higiene del Trabajo By the Ministry of Works (Pp 413 No price) Madrid Seccion de Prevencion de Accidentes e Higiene del Trabajo 1947

An account of industrial health regulations in Spain, in Spanish.

Lehrbuch der Hals Nasen Ohren und Mundkrankheiten By E Schlittler et al (Pp 609 60 Swiss francs) Basle S Karger 1947

A textbook of diseases of the ear, nose, throat, and mouth, intended for students and general practitioners, in German.

Formen und Ursachen der Herzhypertrophie bei Lungentuberkulose By Prof W Berblinger (Pp 183 10 20 Swiss francs) Berne Hans Huber 1947

A monograph on cardiac hypertrophy in pulmonary tuberculosis, illustrated, in German.

Functional Anatomy of the Mammal By W James Leach (Pp 231 12s 6d) London McGraw Hill Book Company 1946

An American guide to the dissection of the cat with an introduction to the structural and functional relationship between the cat and man. Intended as an introductory work for students of anatomy.

A List of Medical Libraries and Information Bureaux in the British Isles By W R Le Fanu (Pp 28 3s) Oxford University Press 1947

Includes addresses, telephone numbers, short notes on the history and present function of the medical libraries and information bureaux.

War Stress and Neurotic Illness By A Kardiner, MD, and H Spiegel, MD 2nd ed (Pp 428 \$4 50) London Paul B Hoeber 1947

A monograph on war neuroses and the treatment of their acute and chronic phases.

BRITISH MEDICAL JOURNAL

EASTER EGG

As a token of rebirth to celebrate the coming of spring and the growth of vegetation many nations in antiquity were accustomed to presenting eggs, sporting with them, painting them, or eating them. Persians, Egyptians, Greeks, and Romans all regarded the egg as a symbol of the universe,¹ and the Jews included it in their Feast of the Passover. Whether the custom was incorporated into the Christian festival of Easter from Jewish or Gentile sources is unknown—indeed it is immaterial, for the egg has no great religious significance to Christians but is merely one of the innumerable symbols taken over from pagan folklore. It is not surprising that primitive man, observing birds and snakes and crocodiles and turtles emerging from an apparently lifeless envelope, surmised that some distant ancestor of his own race had once done likewise. According to an old myth from Bengal the first parents of mankind sprang from an egg, and the Chins of Burma relate that a primeval woman laid 100 eggs from which our ancestors hatched to raise mankind's diverse nations. Primitive Greek myth-makers went further and attributed the creation of the universe to the splitting into two parts of a cosmogonic egg. Phobos and Eros issued from these and created the world and its creatures—a fanciful though perceptive account of an individual's creating his experience, his "world," from his fears and loves. According to the Hermetic tradition the egg round which a serpent twined symbolized the hermaphroditic first principle of the universe, matter-spirit, when apart the former represented Chaos, the latter Ether. The conception of the egg as a link between the animate and the inanimate was taken up by the Greek, and later by the Arabian, alchemists, who saw the egg as a symbol on the one hand of the universe, on the other of the philosopher's stone. Elixir of egg, like the cyclotron to-day, would be capable of transmuting metals. (We note in passing that a recent lecture on "ovobiology" was delivered in Belgium with the title "The Egg will Conquer the Atom!") Sometimes the alchemist referred to his vessel as the philosophical egg in which he heated together opposite elements to form the philosopher's stone. A symbolic analogy may be seen between that process and, if one follows the analytical psychologists in regarding it as a symbol of the mind, the man brooding on the elements of his experience in the creation of individuality. We speak also of a hen brooding on her eggs.

Having endowed his eggs with magic, primitive man was not slow to use them for various medical and other purposes. The ancient Egyptians included eggs in a number of medicaments. The following remedy against sores on

the anus is recorded in the Papyrus Ebers² (written c 1500 B.C.) "Egg of the goose, 1, guts of the goose, 1 Clap on the anus." John of Arderne three millenniums later was recommending white of egg mixed with finely ground flour as a dressing after operating for fistula in ano. Eggs were also popular among the Egyptians as hair restorers and cosmetics, and one face-cream consisted of bullock's bile and ostrich egg beaten up with fresh milk. We need not be surprised that similar concoctions often served the same function in expensive establishments—as "egg shampoos" and "egg packs"—in Britain and elsewhere before the recent war, for primitive ways of thought persist with great tenacity. Black³ has recorded the popular practice of a patient's boiling an egg in his urine and then burying it in an ant-hill. As the egg disappears so does the malady. Again, owls' eggs mixed with a drunkard's liquor will cure him of his evil ways. Ambroise Pare in 1536 found that when boiling oil was not available for treating battle wounds the yolk of egg with oil of roses in turpentine was a better therapeutic trick. Perhaps less remote from our own ideas of the uses to which eggs should be put (though remote from our experience) is William Hunter's predilection for them, his dinner at the British Coffee House consisted of two eggs and a glass of claret.

THE EGG AS FOOD

We want eggs because we like them, we miss the contrast of flavour and texture of intact eggs and the physical properties exploited in cooking. Eggs-and-bacon is a national dish—or at least was, eaten solo, eggs are an equal delight, or they can be combined with other foods in scrambled eggs and omelettes. They satisfy the palate and belly of man, whether he is described as an individual or, in the phraseology of Dr Summerskill, as a calorie-consuming social unit. Their aerating power is used in making sponge cakes, their binding power makes puddings and cakes what they should be, and they for a time stop cakes from becoming stale. The unthinking eater little knows what nutritive value he can extract from an egg. One egg contains about 6 g of protein, equal to the 16% by which our average daily intake of animal protein has fallen since 1938. In a small survey made some four years ago it was observed that it was the families keeping hens who sustained the pre-war consumption of animal protein in their diet. Egg protein is first class. A hen must pack into the shell the protein needed to make a chick that will nearly fill the shell before it can get to other food. For reasons of space the protein must be first class for the chick, if not for other animals. It's a matter of lebensraum.

We read in *Nutritive Value of Wartime Foods* that 1 oz of egg supplies 250 i.u. of vitamin A, this is about 500 i.u. per egg. This statement should have been qualified, for even during the war fowls got varying amounts of carotene in their food, it is from this that the hen gets its vitamin A, and one egg may contain six times as much vitamin A as another. Almost all the vitamin A of an egg is actual,

¹ *Observations on Popular Antiquities* by J Brand. Charles Knight London, 841

² *The Papyrus Ebers* trans C P Bryan G Bles London 1930
³ *Folk Medicine* Folk Lore Society, London, 1893

pre-formed vitamin A, β -carotene makes up about 8% only of the carotenoids that colour the yolk and provides no more than 5 i.u. an egg, but the colour of the yolk provides a rough index of the amount of vitamin in it. Eggs are also one of the few foodstuffs that provide appreciable amounts of vitamin D—about 60 i.u. in egg, which contains also about 0.3 mg. of riboflavin, or one-sixth of our average daily intake. In egg white the protein avidin combines with the vitamin biotin and prevents its absorption, and rats fed on a diet of egg white develop a characteristic dermatitis. A man who lived mainly on six dozen raw eggs a week got a scaly dermatitis, and a similar dermatitis has been produced by feeding people with large amounts of egg white. But there is no risk of biotin deficiency in anyone taking a normal diet, however many eggs are eaten.

Eggs have no ascorbic acid to lose, and the loss of vitamin B₁ in drying appears to be negligible. The physical properties used in cooking may be little changed. The flavours of dried eggs are graded on a scale ranging from "fresh egg flavour, 8," to "inedible, 0." We are told that 75% of people gave a score of 5½ from a sample—between 6 "definite but not unpleasant off flavour," and 5 "unpleasant off flavour"—satisfactory as scrambled egg, and that all domestic eggs now distributed are at least up to this standard. This may well be. But however well the flavour, the nutrients, and physical properties are preserved, dried eggs can never offer the contrasting textures and flavours of whole eggs. Dried eggs smack of utility and austerity.

A laying hen's performance is remarkable. One egg contains as much protein as a pint of human milk, a little less vitamin A, and a little more riboflavin. As converters of the protein of its food to high-class protein for human consumption hens come second only to milch cows, though as converters of calories pigs come first. Hens appear to win as converters of carotene to vitamin A. Cows come first in respect of the B vitamins, for they absorb large quantities of them, manufactured by micro-organisms in the rumen, hens have to depend on what they get in their food as they eat it—a good reason for feeding them with domestic scraps. But the trouble with hens in times of scarcity is that they eat grain that might be eaten by human beings and give no more than a 12% return as calories. In fact we are told that hens will not be content with whole grain but also need the offals left after milling white flour. We have to choose between 85% extraction flour and few eggs on the one hand, and white flour and abundant eggs on the other.

THE EGG AS POISON

Eggs with their apparently impenetrable shells seem to offer us a food safe from the risk of conveying bacterial infection, and were long so regarded. When the Three Musketeers of Dumas feared being poisoned they resorted to boiled eggs as above suspicion. It has long been known that this safety is only comparative, since egg shells are not impervious to bacteria, while some birds get behind our defences by depositing from the oviduct pathogenic bacteria directly in the egg yolk. Many investigations have

shown that ducks may suffer from epidemics of *Salmonella* infections due to strains, such as *S. enteritidis* and *S. typhimurium*, which are responsible for outbreaks of food poisoning in man. Certain varieties of ducks are more prone to these infections than others. The infected ducks may transmit the living bacilli into the egg yolk. In other cases the egg may be infected by pathogenic bacilli passing through the egg shell from outside. Egg shells are porous in the strict sense that they have pores, and many workers have proved the passage through the porous egg shell of bacteria from liquids in which the eggs are soaked. Infected duck flocks have been most frequently met with in Holland and Germany, but they also occur in Great Britain.

Many outbreaks of food poisoning have been shown to be due to the consumption of infected ducks' eggs. Two recent cases are those recorded by R. F. Gordon and A. Buxton,¹ and by E. H. Gillespie.² Much has been done to reduce flock infections by blood agglutination tests, segregation, and the examination of eggs. Hens also may suffer from *Salmonella* infections, but the strains responsible have hitherto been always of *S. pullorum*, a type not pathogenic to man. Unfortunately other strains have recently been encountered. R. F. Gordon and A. Buxton³ isolated *S. thompson* during 1943 and 1944 on 44 occasions from 31 outbreaks in chicks and 2 in ducklings. The organism was not isolated from the eggs themselves. This strain is one which can cause human food poisoning. These findings are in conformity with the fact that at least two food poisoning outbreaks have been ascribed to the egg of the hen, and probably others will occur. They are, however, of extreme rarity, and we may regard the unopened egg of the hen as almost completely safe from being a vehicle for the transmission of disease.

Dried egg powder in tins, now so extensively used to supplement our food supply, is a different matter, and there have been a number of outbreaks of food poisoning from this source. Many investigations have been made into its *Salmonella* content. For example, N. E. Gibbons and R. L. Moore,⁴ examining Canadian egg powder, found *Salmonella* strains in 28 samples (74%), and all but 5 (*S. pullorum*) were potentially pathogenic to man. M. D. Schneider⁵ examined 901 samples of high quality powdered egg used by the U.S.A. armed Forces, and from 32 (3.2%) isolated *Salmonella* organisms, including several strains known to be pathogenic to man. As a means of reducing the *Salmonella* infection the same author subsequently⁶ showed the value of pre-heating the liquid egg at 141°–143° F for six minutes before spraying.

M. Soloway, E. H. Spaulding, and H. E. Goreslar⁷ have recently thrown much light upon sources of infection of the egg powder and suggested lines along which a reduction can be obtained. *Salmonella* organisms were recovered from the shell surfaces of 1% of clean intact shell eggs, from 5% of similar but dirty eggs, and from 5% of "washed-dirty" shell eggs. The same kind of

¹ *Mon. Bull. Emerg. Pub. Hlth. Lab. Serv.* 1945 4 46

⁵ *Food Res.* 1946 11 313

⁶ *Ibid.* 1946 11 521

⁷ *Ibid.*, 1946 11 380

results were obtained when liquid whole-egg mixtures were examined, prepared respectively from the three different grades of eggs. The *Salmonella* strains isolated included many strains known as food-poisoning organisms. These results show that the external shell surface is an important source of *Salmonella* contamination and that dirty eggs are the primary offenders. They also suggest that washing dirty eggs by first soaking in a hypochlorite solution, followed by brushing and water rinsings, is unsatisfactory as a means of removing harmful bacteria. Soaking increases the probability of shell penetration, and subsequent brushing tends to force the organisms into or through the shell pores. Other preventive measures, in addition to using only clean eggs and pre-heating, are the avoidance of delay in tanks of the egg mixture and using correct temperatures of holding. As dried egg powder is likely to become a standardized food it is important that steps should be taken to safeguard its purity. The setting up, and enforcement, of suitable bacterial standards should be considered, and this should not be a difficult matter.

NEW PATHS IN ANAESTHESIA

The conditions in which the art of anaesthesia is carried on in Great Britain are noteworthy. The practice of anaesthesia is restricted to medical practitioners, moreover, they are given the dignity and privilege of being treated as specialists. The wisdom of this course, carried out in the face of opposition, moribund but not yet dead, is apparent from the advances made in this country and the general ferment of inquiry evident in the ranks of anaesthetists. This is in happy contrast to the sad state of anaesthesia on the Continent. This spirit of inquiry is evidenced by the articles published in this issue of the *Journal* on anaesthesia and the relief of pain.

Curare is a word already bandied about by medical students at their finals—a good enough indication that it is a part of everyday medicine and that it has come to stay. The story of its application to clinical anaesthesia exemplifies the old advice to respect the opinion of others while reserving one's own. From the time of Aesculapius to the present day a "big" name over an opinion has often tended to stifle criticism and investigation, sometimes, as history shows, for hundreds of years. Most pharmacologists placed stringent prohibitions on the administration of curare to human beings, and had they been allowed the last word one of the great advances of clinical anaesthesia might have been held back, for example, it was stated in a standard textbook of pharmacology that "the therapeutic use of curare has not been encouraged because of its tendency to paralyse striated muscle." Two articles in this week's issue describe the use of tubocurarine to "soften" therapeutic electric convulsions. They confirm the results of Bennett,¹ who not only put "curare" on the clinical map by using it in such cases but suggested its application to anaesthesia, a still more useful field. It was originally advised that while the curare is slowly injected the patient should be asked to perform some simple movement, like snapping his fingers. When he can no longer do this easily muscular power is waning, and the convulsion can be induced without violent response. It would probably be difficult to improve on such a simple biological test of dosage. Under the cushioning influence of tubocurarine convulsion fractures are almost unknown,

while much of the terrifying aspect of the patient under electro-convulsive treatment is removed, to the benefit of impressionable nurses and orderlies.

The application of tubocurarine to caesarean section is new in this country, although reports of its successful use have come from America. No one would underestimate the gravity of delivering a curarized infant and the problem presented by an apnoeic baby whose lungs, never having expanded, could not be inflated. Such fears cannot be dismissed by one enthusiastic paper. Foetal curarization must depend upon the dose injected into the mother. This in turn is a function of the relaxation required by the surgeon, his operating time, and, not least important, the type of operation—classical or lower segment. What is satisfactory for a lightning operator doing a classical operation may be disastrous for the slower man on a lower segment operation. This is one of the points which emerged clearly from the discussion at the Royal Society of Medicine, reported elsewhere in this issue. All these and other factors must be carefully considered before tubocurarine is advocated as a good adjunct of anaesthesia for caesarean section. In any case, proof would have to be forthcoming not only that tubocurarine is safe for mother and child but that it is safer than, for example, spinal anaesthesia or cyclopropane. The question of the transmission of tubocurarine across the placenta ought to have been settled by animal experiments, but no such experiments are on record. Caution is necessary lest what is old and well tried is jettisoned for something new—just because it is new.

Tubocurarine is a powerful drug. Its most dramatic effects are seen in the vigorous patient, so often a real anaesthetic problem in abdominal surgery, for whom otherwise nothing short of spinal anaesthesia suffices. Tubocurarine has earned its fame by the way it subdues the robust. It is therefore all the more interesting to read of its selective use in poor-risk patients. It may be that in skilled hands and with careful dosage a little tubocurarine may do less harm to such a patient than the little extra amount of a general anaesthetic which would have been needed for the same effect. Nevertheless, the fact will need widespread confirmation before general acceptance. Ill patients, particularly those with abdominal emergencies, often have liver and kidney damage. Any drug must be given cautiously, for excretion is delayed. Already one death has been recorded when tubocurarine was used in a poor-risk case.

Caesarean section and the poor-risk case perhaps represent two of the spots in this new path in anaesthesia which are not quite ready for the heavy traffic of daily routine. Experience will no doubt show others. It is to be hoped they will be well marked for the unwary.

PROGNOSIS IN ACUTE NEPHRITIS

Satisfactory criteria for prognosis in acute nephritis are difficult to obtain. Cure rates of from 38 to 100% have been reported. The different systems of classification, together with the failure to recognize continued kidney damage when the patient is clinically recovered in the "latent state," may account for the discrepancies between various authorities. Snoke^{1,2} has drawn attention to this and to the geographical differences in prognosis reported from the Pacific and Atlantic coasts of the United States. The prognosis of war nephritis, the nephritis of children, and post-scarlatinal nephritis may well vary from that of acute nephritis following infections such as tonsillitis. In selecting

¹ *J Amer med Ass* 1940 114 322.

² *Amer J Dis Child* 1937 63 673
³ *Ibid* 1939 57 1373

cases for follow-up investigations great care must be exercised not to include cases of chronic nephritis with no previous history of acute attack. The whole study of the prognosis after acute nephritis has been hampered by the lack of an agreed procedure for estimating the state of the lesion in the latent symptomless period.

Rudebeck³ has used the quantitative estimation of the urinary sediment introduced by Addis⁴ in 1925, in conjunction with albumin estimation and measurement of the blood pressure and the concentrating powers of the kidney, in his re-examination of cases at the Lund Medical Clinic. In order to free himself from the welter of contradictory material in the literature, he collected from the records of the clinic (1910-39) only those cases which satisfied the following conditions: (a) unquestionable acute nephritis after the age of 10, (b) definite post-infectious onset, excluding specific fevers, and (c) no previous renal disease until three months in most cases, or three years at the longest, before admission to hospital. The material thus obtained was considered to be homogeneous and representative of post-infective acute nephritis in the adult. The criteria for recovery finally adopted were: (a) normal blood pressure, (b) urine albumin-free, (c) an Addis sediment count not exceeding one million red cells per 12 hours, and (d) duration of these negative findings for one year. The figures given for the 318 patients investigated in the follow-up agree well with the majority of previous statistics. Deaths were 6.6% of the total cases. Some 50 patients were not traced. Of the remainder—245 cases—69.4% recovered, 11.0% did not, and 19.6% were labelled uncertain. The interest of the investigation, however, lies in the attempt to estimate the effects of various factors on the prognosis. Rudebeck insists that the results must be evaluated cautiously despite stringent precautions taken to allow for sources of error.

Payne and Illingworth's⁵ views on focal nephritis were borne out. Many patients behaving as cases of focal nephritis progressed to a chronic state. There was no evidence that the severity of the attack influenced the long-term prognosis. The risk of death in the acute stage was much increased when almost complete anuria or heavy albuminuria was seen, but the degree of the hypertension, haematuria, and oedema could not be shown to have any prognostic significance. Osman⁶ believed that recurrent acute attacks of nephritis did not prejudice the recovery rate, and 40 such cases were analysed by Rudebeck. He too found it impossible statistically to prove a bad prognosis in these cases. Pregnancy was demonstrated to have no effect in flaring up a past nephritis, thus agreeing with Wellen, Welsh, and Taylor,⁷ who found that the kidney function was unchanged in two chronic nephritics who went to term. Analysis of the effect of rest in bed showed that patients who were going to progress to chronic nephritis did so whether they were confined to bed early or not, and it could not be proved that the prognosis was any better if the patient was kept at rest for long periods. There was agreement with the view of Addis⁴ that the fate of the kidney is decided when infection occurs, and that treatment has little effect on the eventual course. Tonsillectomy could not be shown to have any beneficial effect in these cases.

From this it would seem that a good prognosis may be given in cases which survive the acute manifestations, of whatever severity, and which recover completely, in Rudebeck's sense, before discharge from hospital. The prognosis must be guarded if residual symptoms are present at

discharge, and if they persist more than one year, or are severe, chronic nephritis may be confidently awaited. Repeated acute attacks, pregnancy, and tonsillectomy were not shown to alter a prognosis made on these lines.

In the literature on nephritis, as Rudebeck points out, "the distinction between knowledge and belief appears not always to be maintained with sufficient stringency." It is to be hoped that further careful studies of this kind will be made which, if in agreement with each other, will afford a rational basis for estimating the effects of treatment and the ultimate prognosis in acute nephritis.

THE SPLEEN AS AN ENDOCRINE GLAND

In the minds of those who lightheartedly extirpate a damaged spleen there sometimes remains a hazy recollection of five pages of "Samson Wright," in which its functions in blood formation or destruction are described—functions which appear, from the excellent condition of the patients afterwards, to be rather unnecessary. The anaemia which supervenes on splenectomy is transitory, as the red marrow soon takes over. The decreased fragility of the red cells, the neutrophil leucocytosis, and the increase in platelets hardly matter. It is usually forgotten that haemorrhage is less well tolerated and that a general feeling of weakness may persist permanently.

Though a severely damaged spleen must still be sacrificed, the recent work of Ungar¹⁻⁴ should introduce a note of regret and doubt into a formerly carefree operation. In 1944 he showed that all the stimuli which inhibit histamine release also reduce the bleeding-time and increase the capillary resistance. The bleeding-time was found to be the most convenient and reliable test of histamine release. It is reduced after tissue injury, and in intact animals by the injection of serum from damaged animals, corticotrophic hormone, or adrenal cortical extract. In hypophysectomized animals, however, trauma is ineffective, whereas in adrenalectomized animals trauma, traumatic serum, and corticotrophin are ineffective though cortical extract still works. It appears from this that in intact animals trauma does something to the pituitary which acts on the adrenal cortex and causes it to inhibit histamine release. Ungar has further shown that if the animal has had its spleen removed all these factors are ineffective, but the injection of splenic extract is effective. It therefore appears that the activity of the adrenal cortex in the response of animals to trauma is mediated by way of the spleen. In 1945 he prepared⁵ a crude extract of spleen and found that its injection into guinea-pigs in appropriate dosage reduced the bleeding-time. The best effect was produced by a dose of 0.3 mg of fresh tissue, but with larger doses the effect was less, and when 100 mg was given the bleeding-time was actually increased. He succeeded in separating the fractions responsible for these opposed results. The increaser of bleeding-time is probably the "thrombocytopen" of Troland and Lee,⁶ which is not released as a result of trauma. The decreaser he calls "splenin." It is a crystalline solid of low molecular weight and melting point which decreases bleeding-time in doses as low as 3×10^{-7} mg/kg, with no reversal at higher dosages. The action of splenin is not inhibited by splenectomy, and its action cannot be imitated by other tissue extracts.

Finding that splenin reduced the bleeding time, increased capillary resistance, and inhibited the release of histamine from blood cells, Ungar proceeded to investigate its effect

⁶ *J Amer med Ass*, 1938, 111, 221

on the mechanism which prevents the breakdown of proteins by trypsin and other proteases. Trauma and injection of splenin increase and splenectomy decreases the antitryptic action of serum. It has been known for a long time that the antitryptic action of serum is suppressed by extraction with ether. The aqueous fraction has very slight antitryptic power, and the ether fraction is practically inactive, but when the two are mixed activity is restored. Two substances are obviously required. The water-soluble one is probably antitrypsin, the ether-soluble one an activator. Ungar found that splenin restores the activity of the water-soluble fraction of serum, and the question at once arises whether splenin is the normal activator of the antitrypsin present in the serum.

Several stages of the argument still require confirmation, but it seems probable from these researches that the normal response to injury is somewhat as follows. The pituitary increases its output of corticotrophic hormone, the adrenal cortex is stimulated into increased activity, the spleen is stimulated to increase its output of splenin, the splenin acts as an activator of antitrypsin, the breakdown of proteins is decreased, with a consequent increase in the production of vasodilators such as histamine⁷, and finally the reduction in circulating vasodilator substances decreases the bleeding-time and the capillary permeability. The relationship between these observations and the alarm reaction of Selye⁸ and the changes in protein metabolism after injury reported by Cuthbertson⁹ and others still need exploration. It seems not improbable that a new window has been opened through which may be viewed from a fresh angle many problems both of surgery and of general medicine.

COLOUR IN FACTORIES

It should scarcely be necessary to argue that the choice of colours both in the decoration of factories and in the painting of factory equipment should be governed mainly by practical considerations related to the particular work to be done rather than by abstract arguments as to the stimulating or depressant effect of specific colours. In a lecture to the Colour Group of the Physical Society in January Mr H. D. Murray approached this subject from a standpoint which industrial medical officers might well find helpful. The essential physiological requirement, he said, was clear vision of the immediate object of work without the strain which must result from any strong contrast between the intensities of local and of background illumination. This applied to the immediate and to the more distant background. Practical experience had shown that in the working surfaces of machines buff provided a satisfactory background for dull steel, an unsaturated blue for brass and an unsaturated green or neutral grey for multi-coloured materials, such as might be encountered in textile factories. The general principle was that the immediate background should be of contrasting colour, and of as high saturation as was consistent with the requirements of equal brightness and avoidance of colour adaptation. The choice was naturally easiest when the working colour was the same throughout a complete factory, and most difficult when material of any colour might be worked in any machine. For the wider background provided by walls and ceiling, the chief requirements were that the colour scheme should be "non-distracting" and that the resulting level of brightness should be substantially uniform. Thus, with typical factory lighting the brightness factor should increase progressively from floor to ceiling 50% being a suitable value for the upper walls and 75% for the ceiling. There was

some advantage in the idea, now fashionable in the United States, of using the colour scheme to emphasize the main structural features and divisions of a factory building. It was important to remember, however, that the main object was to avoid distracting the worker.

Psychological considerations were dismissed as "a convenient justification for a choice for which no immediate reason can be given", but it was accepted that there are shades of yellow which most people dislike. Tests with factory workers had confirmed also the traditional association of greens and blues with coolness, and of red and cream with warmth. There was justification, therefore, for correlating the colour scheme of a factory with probable temperature conditions. Mr Murray made a further concession to the psychological school in reporting that complaints of excessive coldness in a canteen had ceased in one instance, within his own knowledge, after the colour scheme but not the heating arrangements had been altered. If practical experiments were undertaken to assess the popularity of different colour-combinations, it should be remembered that "low interest-value" was for this purpose an advantage. To annoy no one was a more desirable objective than to please, and possibly to distract, a few and, at the same time, to annoy, and probably also to distract, many others. Finally, for anyone interested in achieving the latter result, it seems that a particular shade of crimson may be commended as a foundation.

CEREBRAL PALSY UNIT

The cerebral palsy unit set up by the London County Council in 1943 at Queen Mary's Hospital for Children at Carshalton has been treating an average of fourteen children at a time. It is now proposed to enlarge it to take twenty at a time, and later forty, and later still sixty, by which time it is estimated that between 120 and 150 children will be undergoing treatment each year. A report by the Hospitals and Medical Services Committee of the L.C.C. makes it clear that this unit, the first to be established in the British Isles, has shown that the treatment of selected cases of cerebral palsy by the methods demonstrated by Prof Phelps, of Baltimore, gives good results. Some hopelessly crippled children have been transformed into individuals capable of taking part in the life of at least a school for physically defective children, and in many instances in normal school life.

It is considered desirable to continue with the special methods of treatment now being carried on and to develop the existing facilities as speedily as possible. The Ministries of Health and of Education both want to develop cerebral palsy work, and the latter Ministry has appointed a technical adviser who has been to America to study the methods employed there and the results achieved. A close association has been arranged between the L.C.C. and those responsible for a new school for children suffering from cerebral palsy. This is being established at Croydon by a voluntary organization. In the Carshalton unit the staff is to include a cerebral palsy therapist and an assistant, an occupational therapist, and a speech therapist (half-time). The part-time consultants and specialists concerned will be paid, the physician at the rate of £250 a year for one session a week, and the orthopaedic surgeon at £5 5s a session.

Edward Joseph Conway, D.Sc., M.B., B.Ch., professor of biochemistry and pharmacology at University College, Dublin, and Geoffrey Jefferson C.B.E., M.S., F.R.C.S., professor of neurosurgery in the University of Manchester, were elected Fellows of the Royal Society on March 20.

INTERNATIONAL SYSTEM OF WEIGHTS AND MEASURES

BY

J M HAMILL, MD, D.Sc.

Nearly a century and a half has elapsed since the International System of Weights and Measures was first inaugurated. It is also known as the metric system, because it was based on the metre, but, as will be seen later, this is no longer a correct description on account of modifications which the system has undergone since its inception. After the French Revolution the French Government decided that a rational scientific system of weights and measures which could be used internationally for all purposes was urgently necessary. Accordingly they convened a Commission of representatives of different countries, who in 1799 formulated the international system of weights and measures, or the metric system as it could then quite properly be called. The objects of the Commission were to lay down standards of length, volume, and mass* which should be interrelated and which should be based upon a natural invariable quantity independent of any arbitrary material standard. They chose as their natural quantity a unit of length which was presumed to be the one-ten millionth part of the polar quadrant of the earth which passes through Paris. This unit of length was called the metre and was given material expression in the form of a bar of platinum the distance between whose ends was exactly a metre. This material metre was called the "*mètre des archives*" and remained the standard until 1889. In point of fact the length of the polar quadrant was not exactly known, and the difficulty of repeating the determination of the value of the standard by reference to the definition was so great that it became necessary to legalize the length of the *mètre des archives* as defining the unit, so that actually the standard of length became a material one and not a natural invariable standard as was originally intended.

The standard of volume—the litre—was derived from the standard of length—the metre—or rather from the first sub-multiple of it—the decimetre. The litre was defined as the volume of a cube each of whose sides measured one decimetre. Since a cubic decimetre contains 1,000 cubic centimetres, the cubic centimetre became the term of description for the one-thousandth part of a litre and so remained for just over 100 years, until as will be seen later, the litre was redefined and the cubic centimetre ceased to have any derivative connexion or relationship with the litre.

The standard of mass—the kilogram—was derived from the cubic decimetre. The kilogram was defined as the mass of a quantity of water occupying the volume of one cubic decimetre at the temperature of maximum density (4° C). The material representation of this natural standard was a cylindrical piece of platinum, which was designated the "*kilogramme des archives*" and remained as the standard until 1889. It should be noted that the standard of mass is the kilogram and not the gramme.

The International Commission in 1799 also arranged that multiples and submultiples of the standards of length, volume and mass should bear a decimal relationship to their respective standards in conformity with the decimal scale of numerical notation.

Reconsideration of Standards

The position remained much as stated above during the first three quarters of the nineteenth century. During this period the rapid development of science and technology made accurate measurements imperative and a reconsideration of the international (metric) standards of measurement became urgent. Accordingly preliminary conferences with representatives of about thirty nations were held, and in 1875 representatives of seventeen countries subscribed to a treaty called the Convention du Metre by which an international organization was formed to deal with all questions relating to standards in the inter-

national system of weights and measures. Ultimately thirty-two nations became members of the organization. The organization consists of an international authority—the Conférence Générale des Poids et Mesures—the members of which are accredited delegates of each of the thirty-two nations who joined the organization. This Conference meets normally every six years. They appoint the Comité International des Poids et Mesures, which is an executive body of eighteen members to manage the affairs of the Bureau International des Poids et Mesures between the meetings of the Conférence Générale. This Committee meets every two years, and makes representations to the General Conference or acts on authority delegated to it by the Conference. The Bureau International des Poids et Mesures is the headquarters of the organization, and is situated at Sèvres on a site which has been declared neutral territory and has been ceded by the French Government to the Conférence Générale.

The Bureau International after its formation soon came to the conclusion that the existing standards the original standards of the archives, were capable of improvement, and it was decided to supersede them by new standards. Accordingly in 1889 the *metre des archives* was replaced by the existing standard, which is known as the "prototype metre". This was made as nearly as possible the same length as the *mètre des archives* but it differs in several respects from the old standard. The *metre des archives* was a simple bar of platinum the distance between whose ends was a metre, such a standard is known as an end standard. The prototype metre consists of a bar of iridium-platinum alloy (10% iridium and 90% platinum) whose cross section is X-shaped and near each end on the neutral plane of the bar is ruled a fine transverse line, the distance between these two lines is a metre. Such a standard is called a line-standard. Technical improvements during the nineteenth century made it possible to rule such lines with great accuracy, so that line-standards could be made much more accurately than end standards. When the *metre des archives* was made in 1799 the reverse was the case, line standards could not then be made so accurately as end standards. But the matter does not rest there. It is now possible to make end standards having flat parallel terminal faces with a mirror-like finish of optical perfection so that by interferometric methods the length of the metre can be measured to a degree of accuracy of a wave-length of light. It is, indeed, possible to return to the 1799 Commission's ideal of a natural standard and to express the metre in terms of the wave length of, say the red line in the cadmium spectrum or perhaps the even more monochromatic light of an isotope of mercury. For the present, however, the prototype metre—a line standard—remains the standard in the international system of weights and measures.

Accurate copies of the prototype metre were made and were distributed among the nations who were members of the Conférence Générale. The British copy is No 16, and it is now preserved at the National Physical Laboratory, Teddington. It is the legal standard metre in this country†.

An extremely important change was the redefinition of the kilogram. It had long been realized that masses could be compared with a higher degree of accuracy than volumes could be determined, and the original definition of the kilogram was abandoned because doubt had arisen whether the *kilogramme des archives* did conform precisely to that definition. It was obviously preferable to have a material standard of mass specifically defined rather than one defined from the unit of length through the unit of volume. Accordingly in 1889 the International Bureau constructed a new kilogram which consists of a cylinder of the same iridium-platinum alloy as of the prototype metre, having a mass as nearly as possible equal to the *kilogramme des archives*. This new superseded the kilogram of the archives and is known as the "prototype kilogram", it is the standard kilogram at the present time. It should be emphasized that the prototype kilogram is an entirely independent standard no longer linked with the metre and consequently completely divorced from the metric system.

About forty accurate copies of the prototype kilogram were made and distributed to the countries which were members of the Conférence Générale. The British copy is No 18 and

*Mass is the quantity of matter in a body. Weight is a force expressed as the product of the mass multiplied by the acceleration due to gravity. This latter differs at different places on the earth and consequently the weight of a body at these places differs accordingly.

EVANS

An outstanding advance in
liver therapy

HEPAMINO

The original proteolysed whole liver preparation developed and introduced by The Evans Biological Institute *

For the treatment of all macrocytic anaemias (including refractory anaemia) nutritional deficiencies and as a supplementary food in convalescence

Hepamino is a soluble, pre-digested preparation of whole liver in granular form for oral use

It contains the haemopoietic factors (including folic acid) essential amino acids and water soluble members of the vitamin B complex derived from raw liver

(The representative composition will be supplied on request)

*Brit med J 1944 1 655

Ample supplies of Hepamino are available and with the relaxation of the restrictions on the use of liver it may be freely prescribed whenever desired

In containers of approx 5 oz

NOVUTOX

Self-Sterilising
LOCAL ANÆSTHETIC

$\frac{1}{2}\%$, 1% & 2% SOLUTIONS

FOR

MINOR & MAJOR SURGERY

Absolutely non-toxic in therapeutic doses and tolerated by even the most sensitive tissues. Novutox has the added advantage that it possesses a remarkable chemo therapeutic action which promotes very rapid and clean healing of wounds

Available in

$\frac{1}{2}\%$, 1% and 2% Solutions - - - BOTTLES of 2 ozs and 20 ozs
1% and 2% Solutions AMPOULES 2 cc Boxes of 12 and 100
CARTRIDGES of 2% Solution are available in boxes of 20 and 100

Each cc of Novutox 2% contains 0.02 gm ethocaine hcl
0.00002 gm epinephrine and 0.00002 gm capryl hydro
cupreinotoxin hcl Other strengths of Novutox contain these
elements (with or without epinephrine) in varying proportions

VITAMIN C B.D.H.

There is a close but as yet unelucidated connection between vitamin C and protein anabolism in most, if not all, of its aspects. The formation, growth and maintenance of all protein structures appear to be dependent upon an adequate amount of the vitamin for normal progress. Generous extra-dietary supplements of vitamin C accelerate convalescence, aid in promoting early and satisfactory healing of wounds, burns and fractures and possibly reduce susceptibility to infection by promoting efficient formation of 'antibodies'. Cubic Centimetre versus Millilitre

The next step taken by the International Bureau was the redefinition of the unit of volume, the litre. In 1902 the litre was defined as the volume occupied by a mass of one kilogram of water at the temperature of its maximum density (4°C) and under a pressure of one atmosphere. Since it has been redefined on a basis of the prototype kilogram it follows that the litre, like the kilogram, has been divorced from the metric system, it has now no connexion whatever with the metre. This fundamental change in definition of the litre has the effect of excluding the cubic centimetre from any derivative relationship with the litre. The thousandth part of a litre is now a millilitre and not, as originally, a cubic centimetre. The cubic centimetre should therefore never be used as an alternative to the millilitre. Although the cubic centimetre has now no derivative relationship with the litre or millilitre it is desirable to know what is the volume relationship between the litre and the cubic centimetre. This of course, could be decided only by experiment. In 1910 the International Bureau determined this volume relationship and found that the litre as newly defined was slightly larger than the litre of the archives. Actually it was found that a litre is equal in volume to 1 000 027 cubic centimetres, other determinations give a value of 1 000 028 cubic centimetres. That the litre so closely approximates to the cubic decimetre is evidence of the skill with which the *kilogramme des archives* was constructed nearly 150 years ago.

When it is desired to convert millilitres into cubic centimetres the conversion factor will clearly be 1 000 027, and conversely when cubic centimetres are to be converted into millilitres the conversion factor will be the reciprocal of 1 000 027. This conversion factor is necessary only for work requiring extreme accuracy, for all ordinary medical purposes the conversion factor may be taken as unity. The simplicity of this conversion does not of course, justify the use of the cubic centimetre as an alternative to the millilitre. Apart from the small but real difference in volume between the two, the fundamental reason why the cubic centimetre should not be used as an alternative to the millilitre is the fact that there is no connexion whatever between these two units. The only occasion on which the cubic centimetre can properly be used as a measure of volume is when the volume has been determined from linear measurements. It must be emphasized that the cube of a unit of linear measure as a mode of expressing volume has no derivative or cognate connexion with the litre or any of its aliquot parts.

It is sad to reflect that although nearly half a century has elapsed since the litre was redefined, many people, including regrettably a significant proportion of the medical profession, continue incorrectly to use the cubic centimetre as an alternative to the millilitre. The international system has been legalized in this country and the denominations of the Board of Trade standards of weight and measure which may legally be used are given in the Weights and Measures Regulations, 1907, made by the Board of Trade under the authority of the Weights and Measures Act, 1904. The litre and the millilitre have been legalized but the cubic centimetre has not been legalized as a submultiple of the litre.

The *British Pharmacopoeia* 1932 page 639 follows the legal definitions and recognizes only the litre and the millilitre. The Ministry of Health correctly uses the millilitre in the Milk (Special Designations) Order but in the Therapeutic Substances Regulations 1927 the cubic centimetre is used throughout instead of the correct millilitre. In Article 2 (2) of the Regulations it is stated oddly enough that the millilitre may be used wherever the cubic centimetre is indicated. In other words, permission is given to use the correct unit instead of the incorrect one adopted in the Regulations. The *British Medical Journal* has rightly insisted on the correct nomenclature in its articles and it is to be hoped that other journals which have not yet done so will take similar action. Scientific workers in general have adopted the correct nomenclature and all

scientific glassware made in Britain is now graduated and marked in millilitres, not in cubic centimetres. A curious exception is the marking of hypodermic syringes in cubic centimetres. Clinicians should not lag behind the rest of the scientific world but should arrange with manufacturers to mark syringes in millilitres. Until this is done they should convert their readings into millilitres, using unity as the conversion factor. To record their readings in cubic centimetres suggests ignorance.

No Longer a Metric System

It should be clear from the foregoing why the international system of weights and measures can no longer be correctly described as a metric system. The only part of the metric system which remains is the unit of length—the metre—with its multiples and submultiples, and the squares of these to measure area, and their cubes to measure volume when this is determined from linear measurements. The unit of mass—the kilogram—and the unit of volume—the litre—have been irrevocably divorced from any connexion with the metre. Metrologists cannot evade the logic of this conclusion, but some of them would fain continue to use the description 'metric' mainly as a tribute to the origins of the system. When it is remembered that the metric ideal could not be accurately realized and that one of the ideals of the founders of the system was internationality, sentiment should be satisfied by the retention of this latter aspiration in the description 'international system'. The metric ideal has been shattered by the redefinition of the kilogram and the litre, but the ideal of internationality remains unshaken. It would seem, therefore, on grounds both of logic and of sentiment, that the proper description is the 'International System of Weights and Measures'.

It is interesting to note that there is a close parallel between the kilogram, the litre, and the cubic centimetre and the British weights and measures—the pound, the gallon, and the cubic inch. The pound, like the kilogram, is an independent material standard of mass, the gallon, like the litre, is a measure of volume based upon the standard of mass—one gallon is the volume of ten pounds of water. The cubic inch like the cubic centimetre, is a measure of volume when this has been determined from linear measurements—i.e., inches. The volume relationship between the gallon and the cubic inch, like that between the litre and the cubic centimetre has been determined experimentally—one gallon equals 277.4 cubic inches approximately.

The Question of Spelling

Finally there is the question of spelling, in which there is still a good deal of confusion. The French spelling of *kilogramme*, *gramme*, and *milligramme* is used in certificates issued by the National Physical Laboratory. Certain scientific societies use the English spelling, in which the final two letters, 'me' are omitted. The *British Pharmacopoeia* 1932, uses a mixed spelling—namely, *kilogram*, *gramme*, and *milligram*. The *Pharmacopoeia* is strictly correct in this usage, because this is the legal spelling as set out in the Weights and Measures Regulations mentioned above. This spelling was imported into the Regulations from the Weights and Measures Act, 1878 and the same spelling occurred in the Weights and Measures (Metric System) Act, 1864. The reason for its adoption in this Act is not known. From the point of view of the *Pharmacopoeia* the spelling 'gramme' is fortunate, because it is less likely than is 'gram' to be confused with 'grain,' especially when a writer omits to dot the 'i' in 'grain'. There is much to be said for uniformity in spelling, and if a uniform practice is adopted it should be the legal one used in the statutory regulations of the Board of Trade.

The Manchester Dental Hospital and Turner Dental School, aided by a grant of £30,000 from the trustees of the Nuffield Foundation, will undertake research into the causes of dental disease. Dr Matthews has been appointed to the Chair of Prosthetic Dentistry and Dr Holt to a readership in operative dentistry. The children's clinic at the hospital, by arrangement with the Manchester Education Committee will take over the dental welfare of some 1 200 children attending three schools in the neighbourhood. It is expected that the research will continue for ten years.

MOBILE PHYSIOTHERAPY SERVICE IN LIVERPOOL

In an address to the council of the Greater London Provident Scheme for District Nursing Mr H C R Formby, secretary of the Liverpool "Queen's Nurses" Association, described a mobile physiotherapy service which was started by voluntary effort a year ago. Three units in Liverpool, he said, were now working an average of 44 hours a week each, and each was paying eight visits a day, last year they treated nearly 300 cases (3,560 treatments), nearly all of which had been referred by general practitioners. The object was to provide domiciliary massage treatment for patients unable to attend hospital. Until the introduction of this service under the auspices of the District Nursing Association ambulances and wheeled chairs had had to be used, with consequent delay as well as wastage of manpower. No difficulties were encountered in electricity supply, the apparatus was fitted with adaptable plugs, and for some treatments a portable battery was carried.

In Liverpool they had been fortunate enough to obtain their vans free of cost, and had had to pay only £200 for the conversion of each vehicle. Civil Defence and Red Cross vehicles were still available and suitable for conversion, otherwise, if new vehicles were purchased, the total cost was £500 for each outfit. Running costs were higher in rural than in built up areas, and the aim in rural areas should be to base the unit as nearly as possible in the centre of the district. The maximum fee charged to the patient was 7s 6d for each visit, 5s for those who could not afford to pay the full amount, and necessitous cases were attended free of charge, the cost being met out of public assistance funds. The physiotherapists who of course worked under the instructions of medical practitioners, were not responsible for the upkeep of their vehicles or for the details of administration. Mr Formby said that in his view mobile physiotherapy should be linked with district nursing throughout the country. A committee, to which the Chartered Society of Physiotherapists had appointed representatives, had been set up under the chairmanship of Lord Horder, one of the first objects of which was to raise the necessary funds for areas which could not afford to launch mobile physiotherapy units without aid.

NUFFIELD FOUNDATION FELLOWSHIPS

The Nuffield Foundation is prepared to award a few Fellowships to enable some suitably qualified medical men and women to obtain advanced training in the cause, prevention, and cure of chronic rheumatism. As far as possible, the amount of any award and the conditions attached to it will be adapted to the need of the recipient having regard to the purpose for which these Fellowships are offered. Normally the annual value of a Fellowship will be between £500 and £800. In the event of a Fellow being required to travel abroad to obtain special experience or study facilities the Foundation will pay the travelling expenses involved in addition to the award. Fellowships will be awarded for one year, but may be renewed for a second year, and are open to men or women who are British subjects holding a medical qualification registrable in the United Kingdom, and who are normally resident there and who desire to specialize in the diagnosis, treatment, and study of chronic rheumatism. Candidates must have spent at least one year since qualification in the general medical practice of a hospital, and preferably should hold the M.R.C.P. diploma. A Fellow may not hold any other award concurrently with the Fellowship without the permission of the trustees of the Foundation. Fellows will be required to carry out, at institutions approved by the trustees of the Foundation, a programme of work and training similarly approved. Other work, paid or unpaid, may not be undertaken without the permission of the trustees. A Fellow will be required to submit to the trustees, at the end of each year's tenure of his Fellowship, a report on his or her work during that year. Should the trustees at any time find that a Fellow neglects or has neglected the obligations of his appointment, they shall have power immediately to terminate his Fellowship. The Foundation is prepared to receive applications at any time. Medical officers at present serving with the armed or auxiliary Forces of the Crown may apply for Fellowships tenable on their release from such Forces. Forms of application are obtainable from the Secretary, Nuffield Foundation, 12 and 13, Mecklenburgh Square, London WC1.

Preparations and Appliances

CUTTING PUNCH BIOPSY FORCEPS

Dr J WALTER, Deputy Medical Director, Sheffield National Centre for Radiotherapy, writes: This instrument was designed for speed in taking biopsy specimens from surface lesions, particularly neoplasms. It is essentially a modification of the ordinary punch forceps with the following differences: (1) The lower half ends in a lancet point with sharp tip and cutting edges, the blade approximates a scalpel in thickness. (2) The upper half corresponds in shape, but is a "ring" allowing the lower blade to sink into it, to produce a shearing action. The lower edges of the upper ring are sharpened to produce the cleanest possible shear.

To illustrate its action on, say, a skin epithelioma the lower cutting blade is pushed in deep to the growing edge, to the desired depth and distance, and the upper ring is brought down scissors fashion, shearing off the piece of tissue above the cutting blade, and the specimen is lifted cleanly away. The

whole operation is completed with one hand in a few seconds, and usually no local analgesia is necessary. Its advantages are marked, as compared with the ordinary two-handed method with scalpel and dissecting forceps: (a) There is no danger of missing the selected fragment, or of macerating it by repeated incision and manipulation. (b) Bleeding cannot interfere with the speed and success of the operation once the blade is correctly inserted. (c) An adequate depth of tissue, suitable for a definite histological opinion as to invasion of corium is more likely to be secured than by the ordinary method. (d) The speed and ease of the operation make it particularly valuable in a busy out-patient department, where routine biopsies would otherwise be impracticable. (e) A wider field of biopsies is opened up, for example, from the pharynx, back of tongue, vagina, where time-consuming methods are generally needed. It is particularly useful inside the mouth.

Experience over two years in a busy department has demonstrated its value. The edges can be sharpened as necessary, and sterilization secured by immersion in lysol instead of boiling.

The instrument was manufactured by Messrs Wm Skidmore and Co., Ltd., 59, Cemetery Road, Sheffield, 11. A fuller description has appeared in the *British Journal of Radiology*, May, 1946, and I am indebted to the Hon. Editors for permission to make use of the material previously published.

La Ligue Internationale Contre le Rhumatisme has now been constituted under the presidency of Dr Ralph Pemberton, of Philadelphia, and subdivided into a European "Ligue" and an American "Ligue". The British branch will be represented by the scientific advisory committee of the Empire Rheumatism Council with the following officers: *Chairman and National Representative* Dr W S C Copeman, *Treasurer* Dr G D Kersley, *Secretary* Dr Oswald Savage. A European congress has been arranged in Copenhagen for September this year and an international congress in the United States for 1949. As far as possible all old members and others who may be interested have been circulated, but the Ligue is anxious to enrol any medical men concerned in the problem of rheumatism. Further details will be sent on application to the organizing secretary, Empire Rheumatism Council, Tavistock House (North), Tavistock Square, London, WC1.

Reports of Societies

ANAESTHESIA FOR CAESAREAN SECTION

A discussion on anaesthesia for caesarean section took place at a meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine on March 21. The subject excited unusual interest, the seating accommodation in the Barnes Hall was extended to capacity and over 100 members stood throughout the proceedings. The chair was taken by Mr WILLIAM GILLIATT.

Spinal Anaesthesia

Mr RUFUS THOMAS said that the criteria in anaesthesia for caesarean section must be primarily the safety of the mother and child and, subject to this, ease of operating for the surgeon. Nearly all his caesarean sections for nine years had been done under spinal anaesthesia with "nupercaine." He admitted that spinal anaesthesia was not suitable for any and every woman. It was said that the pregnant woman at or near term was susceptible to the influence of cocaine products, "nupercaine," however, was a quinoline product not related to cocaine compounds. It was also said that collapse and death were liable to occur from a sudden drop in blood pressure. This might be so if proper precautions were not taken, it was a danger to be avoided first by giving a vasopressor before the injection, by having the blood pressure recorded at five-minute intervals throughout the operation with injection of a vasopressor if the systolic pressure dropped below 90 mm Hg and finally by the elementary precaution of not using spinal anaesthesia in unsuitable cases. It was dangerous to use it in severe anaemia or low blood pressure unless and until the patient's condition could be restored by blood transfusion.

With these precautions spinal anaesthesia was safe and easy to administer. The difficult cases were those with spinal abnormalities. The patient herself felt nothing after the initial prick of the needle. She was, of course, conscious. She heard the baby cry at birth she could be told its sex, could see the baby herself if she desired and could see her husband at once. The anaesthetic had no effect on the baby. He had heard many infants cry lustily before being delivered from the uterus. The surgeon moreover, had the maximum of operative comfort. The muscles were relaxed, the abdomen quiet, and access to the lower segment was greatly facilitated. Some operations were almost bloodless. The placenta often delivered itself, and closure of the uterine and abdominal incisions was very easy. After operation vomiting and distension were rare and chest complications practically non-existent. He was able to speak of 346 caesarean sections under "nupercaine." There had not been a maternal death under or due to the anaesthetic. The number of infants delivered (including four sets of twins) was 350 of which 2 were stillborn and 10 died later, an infant salvage rate of 96.5%. The chief indication for operation was disproportion, but a "spinal" had been used in practically all the recognized indications for caesarean section, including a number of cases complicated by ovarian cysts and 58 cases of placenta praevia. Caesarean section under spinal anaesthesia was carried out twice for 41 patients and three times for 5.

Caudal Anaesthesia

Mr J. H. PHEL reported a small series of cases in which caesarean section had been carried out under caudal anaesthesia. He could not claim that this was a perfect method, but it was a valuable addition to the anaesthetist's technique, giving a systematic and unhurried approach to the lower uterine segment. The dangers of ether, chloroform and "pentothal" (thiopentone) in producing foetal narcosis needed no emphasis. There was a growing conviction both in America and in this country that general anaesthesia was not advisable for caesarean section. The Philadelphia General Hospital reported that fewer and fewer women were being subjected to inhalational anaesthesia. He was prepared to admit the advantages of spinal

anaesthesia, and some American and British figures were excellent, but it was difficult to rid one's mind of tales of disaster. The caudal approach completely eliminated meningitis and other risks. But it was a method which called for great care and experience if good and certain results were to be obtained by injection into the sacral canal. From 20 to 40 minutes were required from the start of injection until the patient was ready for the surgeon.

He described 50 cases operated on at King's College Hospital, with no maternal mortality and no more morbidity than in caesarean section in general. There were no stillbirths, but there were three neonatal deaths, due to prematurity in one case and to a diabetic condition of the mother in two. Haemorrhage was minimal. The baby cried immediately, there was no narcosis or anoxia. Atelectasis and pneumonia following inhalation of liquor were reduced to a minimum. The Trendelenburg position could be safely used—a small but important advantage. Various methods of premedication had been tried, but patients were far less worried if they had no premedication at all than if they had small doses of drugs which rendered them more excitable. Apart from local abnormalities and difficulties in locating the sacral hiatus, the two most important contraindications were recent haemorrhage and low blood pressure. Patients should be given 1/4 gr (16 mg) of morphine as soon as the child was born. The most important drawback to the method was the expertness demanded in administering the injection, nevertheless he urged that it be given a more extensive trial especially by those who were of opinion that spinal anaesthesia was dangerous for women during pregnancy.

Dangers of Inhalational Anaesthesia

Mr C. MACINTOSH MARSHALL said that there were several reasons why inhalational anaesthesia must be judged unsatisfactory and even dangerous. Most inhalational anaesthetics induced some degree of anoxia. This was of little importance as a rule but sometimes as a result of laryngeal spasm or vomiting the anoxic state was quickly reflected in the infant. In addition, many babies came under the influence of the anaesthetic and some resuscitation was required, and occasionally might not be effective. At the same time, in the case of the perfectly sound woman operated on before the onset of labour, these dangers were not likely to arise given an expert anaesthetist. This last qualification was important, because the great majority of anaesthetics for caesarean section were given by the residents in the various hospitals. When, on the other hand, labour had been prolonged, poor uterine action had been a prominent feature, a large amount of sedatives had been used, and extreme moulding was present, the dangers were enhanced and general anaesthesia was absolutely contraindicated. The foetal risk required no emphasis. The only justifiable choice lay between spinal and local anaesthesia. Spinal anaesthesia was almost ideal, but deaths were still reported in literature, and, as he had reason to know, not all the deaths under spinal anaesthesia in caesarean section found their way into the literature. For his own part he had never seen spinal anaesthesia have the slightest adverse effect on the foetus, and no doubt accidents could be avoided, but there were fatal cases.

Local anaesthesia was the method of choice for the intra-peritoneal lower segment operation. He hated local anaesthesia—always had hated it—but he had to try to do what he believed was safest for the mother and child, and among the hundreds of contributions that might be written on the subject of that night's discussion he did not believe that there could be one on the dangers of local anaesthesia in caesarean section, because those who used the method would have no cause to make such a contribution and those who had not used it would not have the courage to do so. He pleaded therefore that local anaesthesia should be considered, particularly when it was important to give the premature child every chance of survival. It promised the normal and therefore the best, oxygen supply in the mother's blood so long as the baby was dependent upon the placental circulation. For many years he had given no pre-operative sedative, but to ameliorate the rigours of the local anaesthetic he had sometimes given a little "pentothal" (thiopentone) just before incision of the uterus. So far he had seen no harm to mother or child.

Experience with Various Methods

Miss KATHARINE LLOYD-WILLIAMS brought forward the records of 305 cases from the Royal Free Hospital. Of these cases 224 related to the pre-war period 1931-9. The anaesthetic procedures adopted had gone through various changing phases which she described. At one time she gave nitrous oxide and oxygen until the baby was born then went on to chloroform, and after delivery completed the anaesthesia with gas and oxygen and ether. She stressed the need for complete confidence between the surgeon and the anaesthetist. Later she had tried spinal anaesthesia with results which from the surgeon's point of view were very satisfactory. Spinal anaesthesia became the routine method in her department, using a solution of 1 in 2,000 "nupercaine," preceded by a small dose of "omnupon" and scopolamine and followed post-operatively by paraldehyde. During the war years certain modifications were made, cyclopropane was tried, but was not a popular anaesthetic. She described in detail the present routine method in which thiopentone was used with gas and oxygen. "Omnupon" was given intravenously after delivery, and the operation was completed with a further dose of thiopentone if necessary. She concluded with the observation "As I grow older I ask myself, before giving an anaesthetic, would I like it myself? So far as concerns spinal and local anaesthetics, which for special cases are admirable, my answer is No."

Dr MASSEY DAWKINS said that the question as to which was the best form of anaesthesia for caesarean section must evoke considerable argument, and every known method had its advocates. A search of the literature had brought to light only one large series of cases in which the results were tabulated according to the anaesthetic used—he referred to that published by Irving, of Boston. He went on to give a closely detailed account of the various procedures followed at University College Hospital, including the use of epidural analgesia in caesarean section. Gas and oxygen and ether were most often used. Local anaesthesia had not been entirely successful; only 37% of the patients were able to stand the operation without further anaesthesia. He concluded by saying that he had yet to meet an anaesthetist who would choose to have a spinal anaesthetic for himself, and he added that the anaesthetist had failed in his duty towards his patient if the baby was unable to cry on delivery.

More Advocacy of Spinal Anaesthesia

Dr J. N. CAVE supported the case for spinal anaesthesia. If an inhalational anaesthetic was used the least amount possible should be given in the shortest possible time before the foetus was delivered. He was convinced that, when there was no contraindication, a spinal anaesthetic gave the greatest chance of a successful delivery with a minimum of risk.

Mr H. J. MALKIN gave a preliminary communication on experience at Nottingham with spinal anaesthesia in caesarean section. For the last eighteen years he had used spinal anaesthesia almost exclusively for major gynaecological and obstetrical operations. He had particulars of 767 consecutive unselected cases of caesarean section in 736 of which spinal anaesthesia had been used. There had been 8 maternal deaths, none of which could be said to be due to spinal anaesthesia *per se*. All types of cases appeared in this series including emergency operations. Mr COCHRANE mentioned 517 cases in which spinal anaesthesia had been employed. The drug used in the large majority of cases was a procaine derivative. No death was recorded in this series nor any particular collapse, which suggested that procaine derivatives were not as noxious for the patient as was sometimes supposed. Very small doses were used and gave 40 minutes' operating time.

Mr J. A. STALLWORTHY complained that speakers had not differentiated between the lower segment and the classical operation. These constituted completely different entities. Nobody had mentioned the danger of asphyxia of the child due to spinal anaesthesia. The better the spinal anaesthesia the more the uterus was cut off from central control and the more it was likely to go into spontaneous contraction. He had seen foetal distress become immediately apparent, and on two occasions it was impossible for the child to breathe in a lower segment

operation because the uterus was in atonic contraction. It seemed to him that what was much more important than the virtues of one particular type of anaesthetic was the choice of anaesthetic.

The chairman, Mr GILLIATT, in closing the discussion, said that anaesthetists were dissatisfied with the older and more usual methods employed in general surgical procedures. Some of them had carried out the operation with complete satisfaction to the patients when the anaesthesia was administered by any of the different methods advanced that evening. But he could not help feeling a distinct liking for an anaesthetic which did not involve inhalational methods. He felt that many of them would go away dissatisfied with the methods to which they had been accustomed, but stimulated by the accounts of methods so strongly recommended by others.

TUBAL PATENCY TESTS

At a meeting of the Devon and Exeter Medico-Chirurgical Society on March 20 Dr MARGARET H. JACKSON discussed the value of tubal patency tests in the diagnosis and treatment of sterility. She referred to the pioneer work in this field of Ruben, Bonnet, Gordon King, Sharman Meaker, Sicard and Forestier. Tubal morbidity as a factor in infertility was estimated by some of those authorities to be more or less important in nearly 50% of all cases. In a series of 570 cases in which she herself had carried out tubal patency tests Dr Jackson did not place the incidence of all kinds of tubal morbidity (including complete occlusion partial or temporary occlusion by spasm or stenosis, and lack of normal tubal peristalsis) much above 30%, a figure lower than that of most workers. Moreover, of these total organic occlusion after repeated patency tests was present in only about 10%. If the tubal patency tests were not carried out as a routine an essential causative factor in some cases of sterility would be missed. It should be remembered that the indications for testing tubal patency were not only diagnostic but also therapeutic, for a much desired pregnancy not infrequently followed. Acute pelvic infections contraindicated patency tests.

The best time to do them was during the middle third of the menstrual cycle, well away from menstruation, as near ovulation as possible and preferably just before it. With the patient in the lithotomy position a bivalve plastic speculum was inserted. Not more than 150-200 ml of CO₂ should be used and pressure should never exceed 210 mm Hg. Gentleness and asepsis were essential, antispasmodics should be given whenever there was evidence of spasm, but anaesthesia, with a very few exceptions was unnecessary—indeed it was a disadvantage, because the patient's co-operation was required. Moreover anaesthesia was of no value in the relief of tubal spasm. Pain was slight—rather like that of mild dysmenorrhoea—unless there was obstruction or unless pressure was raised unduly where upon mid-hypogastric pain, sometimes referred to the sacrum or iliac fossae ensued. Late effects included referred shoulder pain on sitting up which was transient and seldom severe, or after lipiodol, pelvic and sacral aching.

Repetition of Tests

The importance of carrying out repeated tests before accepting a diagnosis of complete occlusion could not be over-stressed. Tubal insufflation and lipiodol injection were complementary tests. Insufflation was inexpensive not troublesome and took only about 15 minutes. With a regularly tested kymograph apparatus peristaltic movements, spasms and stenosis of tubes could be accurately recorded. A vulsellum hardly ever needed to be used. By insufflation alone one could not be sure if both tubes or only one was patent, nor could a block be located. Air embolism and sepsis were possible but avoidable dangers. By means of utero salpingography the shape size and position of the uterus and of the cervix could be visualized. Filler defects and spasticity shown, fixation of the uterus demonstrated by screening, the length and tortuosity of tubes and points of obstruction or occlusion noted. Moreover lipiodol had a therapeutic effect. In discussing the aetiology of tubal morbidity Dr Jackson emphasized the importance of tubal culosis of the uterus and tubes which was often "silent" and of which no history could be obtained.

Correspondence

The Toxicity of Iron Compounds

SIR—The paper by Dr Gilbert Forbes (March 22, p 367) has drawn attention to the toxic action resulting from accidental overdosage of ferrous sulphate taken by mouth. No mention is made of the name of the preparation, but we believe we are correct in saying that it was "fersolate" tablets, of our manufacture.

Experiments in progress in these laboratories indicate that for the more soluble iron compounds the toxicity is closely correlated with the iron content (calculated as ferrous iron) and strongly suggest that the action is due to the formation of ferric chloride in the stomach. The iron compounds were given, either in solution or suspension, to fasting rabbits by means of a stomach tube, the doses were adjusted to body weight. According to the dose, the animals either died in a few hours or recovered completely. The post mortem findings for those that died were completely in agreement with those of Forbes, the cause of death being haemorrhagic gastritis. The animals that recovered were quite well on the following day, daily blood counts and urinary examination showed no abnormal findings. In some cases but not all, the stomachs of these animals showed signs of irritation at the great curvature.

The results so far obtained indicate that the fatal dose of ferrous sulphate in rabbits is higher than those reported by Forbes for guinea pigs. We find that "fersolate" tablets compare favourably for toxicity with other iron compounds so far tested and the presence of small amounts of copper and manganese sulphates does not increase the toxicity, which is due to ferrous sulphate. The toxic effect of the iron in Bland's pills is less than half that of other ferrous salts, but relatively higher doses are required for haemopoietic action.

The lower toxicity of Bland's pills may be due to the sodium sulphate in this preparation having a cathartic action that hastens the excretion of the iron. Rabbits treated with high doses of Bland's pills had a profuse diarrhoea within half an hour of dosing. It would appear, therefore, that a gastric lavage with an alkaline solution would be of value after accidental overdosage with ferrous sulphate. This would neutralize the acidity of the stomach, cause precipitation of ferrous carbonate, and prevent the formation of ferric chloride and retard the absorption of iron.

The results of further experiments, now in progress, will, it is hoped, be published in detail later.

Ferrous sulphate is one of many medicinal substances having undesirable effects when taken in grossly excessive quantities. We consider that Dr Forbes's paper serves to emphasize the need to keep such preparations out of reach of young children, and to guard against overdosage—I am, etc.

Greenford, Middlesex

G F SOMERS

SIR—Dr Gilbert Forbes (March 22, p 367) has written a very important paper which has wide reaching implications. Have we not been assuming too much that "harmless" drugs are innocuous even in large doses and that the excess will be excreted without danger? The outstanding example is the vitamins which are found only in traces in natural products, and yet are prescribed medicinally in enormous quantities.

To return to the ferrous sulphate question I remember some 12 years ago being stimulated by Dr Helen Mackay's papers on anaemia in infants to order massive doses of ferrous sulphate as a routine procedure during the last months of pregnancy. After some months I abandoned this as a number of women complained of headache, nausea and malaise and if the iron was continued developed a mild albuminuria. I was convinced that there was an association between these liver and kidney symptoms resembling a pregnancy toxæmia and the excessive iron intake but I must acknowledge that I did not find anyone to agree with me. However I have never given large quantities of iron in pregnancy since, and in the light of Dr Forbes's cases

with the reported damage to liver and kidneys I venture to bring up this theory once more and to ask whether anyone else has had a similar experience?—I am, etc.,

London W 8

VIOLET RUSSELL

Retrodisplacement and Fertility

SIR,—There is not the slightest doubt that retrodisplacement of the uterus is a cause of sterility. A woman with a backward displacement of the uterus can become pregnant but if she is sterile and a backward displacement is present, the correction is followed by pregnancy in a very large number of cases. Needless to say, full investigation of both male and female is a necessity—I am, etc.,

Dublin

BETHEL SOLOMONS

The "Costoclavicular Syndrome"

SIR,—Prof E D Telford and Mr S Mottershead raise in their paper (March 15, p 325) several interesting points and advance new concepts of great importance to a proper understanding of the various factors involved in cases of brachial neuralgia. Probably owing to the paper shortage clarity has been sacrificed to compression in certain places.

The authors describe the operative findings in fourteen cases associated with cervical rib and extensive arterial thrombosis, except in two cases the thrombosis extended no higher than the lower border of the pectoralis major. Are these findings meant to imply that the cervical rib played no part in the syndrome and that no case of arterial damage due to cervical rib was found in this extensive series? Is it believed that the arterial damage was due to compression between the heads of the median nerve and that this was due, either directly or indirectly, to the fact that the cervical rib altered the relationship between the plexus and artery?

The stated "textbook picture of neurovascular bundle compression" fails to convey what is found in practice. In our experience there is no such picture. These cases differ considerably in history, symptomatology, and signs, and this difference has valuable diagnostic implications. The authors are undoubtedly right in casting doubt as to whether their remaining 69 cases of cervical rib were in fact correctly described. Prof J R Learmonth's recent paper in *Thorax* undoubtedly gives a balanced judgment of this problem.

We believe that the case in which the axillary artery was compressed by the two heads of the median nerve is the first to be described and as such is of considerable importance. It might be helpful to consider this concept from its obverse angle. Consideration of the respective resistances of artery and nerve would lead to the expectation that symptoms would arise from the nerve rather than the artery in such a case. From the rather meagre clinical data provided it appears likely that this in fact happened. It might be preferable to contend that the median nerve was compressed by the artery. In fact quite possibly this man's symptoms might have been alleviated by resection of his first thoracic rib, as this would have led to alteration of the artery-plexus relationship.

The challenging statement that in postural manoeuvres of the shoulder resulting in obliteration of the radial pulse the axillary pulse can still be felt cannot be allowed to pass unquestioned. A small personal experience does not suggest its general validity and it is contrary to certain published evidence. It is not clear from the text or the table whether the authors in fact ascertained in each case where the radial pulse was obliterated that the axillary pulse was still present and undiminished. Further information on this point would be welcome and in particular if in fact all cases had not been examined, on which cases this statement was founded. Further, the statements in the summary, paragraphs 2 and 4 are contradictory. Paragraph 4 is almost certainly a misprint as the references quoted include several undoubted cases of costoclavicular compression noted at operation. The role of costoclavicular compression in causing a rise in venous pressure in the arm requires consideration (Sampson *et al* 1940). The evidence as a whole is suggestive that costoclavicular compression is common and cannot be disregarded. It is noteworthy that the rise of venous pressure on bracing back the shoulders cannot be attributed to median nerve compression. It is considerably lessened if the first rib is missing as in thoracoplasty. In these cases the average rise

in pressure was 2.3 cm of water, while the rise in 26 normals was 6.7 cm of water

The section dealing with the anatomical dissections is interesting and informative but, in a way, unsatisfactory. A considerable amount of work has not been utilized to its full extent. Nerves are described as being "tightly stretched"—tension can be measured, the clavicle moves from the rib—distance and angles can be determined. Kelvin, throughout his life, stated a great though limited truth: "Science is measurement." There is no doubt that the rational assessment of anatomical problems is profoundly aided by the discerning analysis of even necessarily imperfect measurements. That this problem is not easy is appreciated, since we have been interested in its complexities and difficulties for some time. Telford and Mottershead have undoubtedly done a first-class piece of work, and this is properly acknowledged in your leading article, but their answers to some of the questions we pose would also be of great interest.—We are, etc.,

Curare

SIR,—Dr Massey Dawkins (Jan 18, p 111) has drawn attention to a condition of shock, as reported to him by nurses and ward sisters, among patients who have received curare, which, he says, is probably due to insufficient anaesthesia. The letters from Dr A J Gray (Feb 1, p 196), Dr H G Kahlenberg (Feb 8, p 234), and Dr G V S Wright (Feb 15, p 268) point to this condition of shock as being due to the profound muscular relaxation and anoxaemia from depression of respiration. Dr D S Jones (Feb 15, p 269) suggests that post-anaesthetic complications may be due to an overdose of curare. From this one infers that the condition of shock results from overdose of curare.

From these three theories surely far the most plausible is the second as proposed by Drs Gray, Kahlenberg, and Wright. No patient should ever be allowed to return to the ward in such a condition, no matter what anaesthetic has been used. Precautions must be taken in the theatre during and at the close of the operation to counteract it, otherwise such excellent drugs as cyclopropane and curare become a veritable menace and fall into undeserved disrepute.

Certain points in the induction, maintenance, and recovery from anaesthesia where curare has been used seem pertinent. Where maintenance is to be by "pentothal" and endotracheal oxygen it seems important to administer enough curare to obviate laryngeal spasm and straining at the commencement of the operation, too little may lead to difficulties in intubation, with subsequent mis-use of the drug's potent qualities and an upsetting of technique. Controlled respiration is then performed, and as soon as automatic respiration is resumed the partial rebreathing technique is resorted to, oxygen being the only gas inhaled. The soda lime is then used in accordance with the desirability or not of quiet breathing. In this way the carbon dioxide in the circuit causes dissociation of oxygen from oxyhaemoglobin in the tissues. Tissue asphyxia and hypotonicity with diminished venous return are mainly due to depressed respiration leading to anoxaemia. This I submit is most often caused nowadays not from overdose of drugs but from the use of prolonged carbon dioxide absorption and endotracheal tubes.

Except in the case of certain operations, among which I would include those demanding the full Trendelenburg, the use of an endotracheal tube certainly predisposes to diminished respiratory excursion from the necessity of having to use more curare. It seems therefore wiser not to use an endotracheal tube as a general rule, thus cutting down the amount of curare required, using only sufficient to procure adequate muscular relaxation, and to use only minimal doses of "pentothal." An endotracheal tube is not normally necessary provided an adequate airway is ensured, as in any case curare counteracts reflex laryngeal spasm even though a muscle-relaxing dose might not be sufficient to allow direct laryngeal intubation.

During maintenance the soda lime should be cut out of circuit and the tissues given the benefit of carbon dioxide either self-generated in a cyclopropane anaesthesia or from a cylinder with the expiratory valve open in a "pentothal" oxygen administration. With cyclopropane maintenance only sufficient curare is used to procure relaxation and the soda-lime is periodically cut out when ever the respiratory excursion can be deepened. Air is admitted to the circuit before the close of the operation and further amounts of carbon dioxide used to help eliminate the anaesthetic. If respiration is still depressed there should be no hesitation in giving physo-

stugmine and atropine intravenously before returning the patient to the ward.

Finally in cases where respiration is markedly depressed or where the blood pressure is not within 10 mm Hg of the pre-operative level and where the pulse pressure is below 30, the usual clinical evidence of shock being present, intravenous plasma or adrenaline drip should be instituted without delay. Curamine and oxygen are prescribed and house surgeons warned to withhold the use of morphine until the patient has fully recovered and it is certain that any restlessness is due to pain. For less serious degrees of shock warmth and raising the foot of the bed and a rectal saline drip are measures to be instituted. As soon as possible the patient should be encouraged to sit up and moved from side to side and remedial chest exercises instituted, as pulmonary complications are prone to develop following upon such a condition of shock.

I have been interested to find that in one or two cases this condition of shock has been associated with a marked diminution in pulse rate to the region of 50 beats a minute. This is a common finding in cyclopropane overdose and may possibly be an indication of "pentothal" overdose as well, though I have not been conscious of administering an overdose in this respect. Again I can only surmise that the condition is due mainly to anoxaemia or oxygen lack in the tissues, occasioned by diminished respiratory exchange from too much carbon dioxide absorption, leading to a diminution in peripheral resistance. Curamine acts centrally so must be reinforced with an additional supply of oxygen. I would be interested to hear whether other anaesthetists have also experienced this state of affairs.

—I am, etc.,

Bristol

W M MAIDLOW

Clinical Freedom and the Board of Trade

SIR,—The Minister of Health recently declared that "it is a basic principle of the new Service that there should be no interference with the clinical freedom of any doctor—specialist or general practitioner." Why then has the Board of Trade this week issued an instruction as to the type of case for which a spinal support may be prescribed (*Supplement* March 15, p 33)? Thirty-nine diseases and deformities are listed, ranging from actinomycosis of the spine to ureterostomy. Apparently there will be no problem in securing a surgical appliance for spinal neurosis! Many of us may think that no treatment could be worse but at least the Board of Trade has no objection. It is also gratifying to learn that a surgeon will have no difficulty when he makes a diagnosis of actinomycosis of the spine (of which I know of only six records in the literature of the world) a simple prescription will suffice. But for the scores of patients seen week by week and month by month with prolapse of an intervertebral disk, such a prescription will not be accepted. The surgeon must prepare "a fuller medical certificate," give "the precise condition," add "sufficient detail" send it to Horseferry Road where the Board of Trade will examine it, and submit it to the medical advisers of the Ministry of Health who in their wisdom will deliberate and in due course pass judgment, and then send it back to the Board of Trade for endorsement, who will return it to the surgeon and possibly grant permission for him to refer it to his instrument maker. Does anyone believe that such a proposal is calculated to promote honesty in the minds of surgeons, or is it obvious that sooner or later the alternative of subterfuge will be adopted, and no matter what the true diagnosis may be, a suitable label will be found in one of the 39 listed conditions which is less of an untruth than others and the prescription made accordingly?

In short I do not complain that one of the most common of all spinal disorders has been left off the list, I complain that such a list has been made at all. I complain of legislation of such a type as to bring legislation into contempt. The object could have been achieved more successfully by reminding doctors that certain materials are still in short supply and that care is still needed in prescribing spinal supports and corsets. A simple letter of 20 words, conforming to the traditions of the profession, would have done much more than this blundering 500 word document with its central direction and civil service control.—I am, etc.,

London W 1

REGINALD WATSON JONES

Certificates for Corsets

SIR,—With laudable objective in mind brewers allocated a proportion of available supply of spirits for medicinal use supplying and designating same as such and providing such

dition to the quota available for ordinary use to the distributor. Only they forgot that an unscrupulous publican can inhibit all ordinary sales and provide distribution only by provision of a medical certificate for same, and as his supply of the latter is reimbursed for each medical certificate provided, the more medical certificates he receives the greater facility he is provided with to dispose of his weekly quota at gratifying prices to himself. That honest hostellers do exist distributing their quota in fair portion to all their customers while still reserving a small percentage for immediate essential medical use, rather proves that the original reservation is not essential nor in fact desirable.

This allegorical approach enables me to state with conviction that I have never seen half a valuable page of the *Journal* put to a greater degree of useless blather than is contained in the supplement of March 15 (p. 33) describing what is apparently a face-saving measure for the original restrictions imposed on such an essential female garment as a corset, such measure in any case still stimulating the corsetiere to obtain a quota-free corset for her client in preference to the private made-to-measure article, as the former is still apparently available free of purchase tax.

I note these arrangements have not been drawn up in consultation with the manufacturers, and venture to suggest that their advice might have been taken as to how they have successfully surmounted the prolonged epidemic of "severe isceroptosis" despite their shortage of skilled labour. The matter undoubtedly may now be left to their initiative in the confidence that essential demands will be met and the initiation of isceroptotic anxiety left to the hands of the charlatan—I am, etc.,

Tipton Staffs

L. H. EUNSON

Diet and Canine Hysteria

SIR—Sir Edward Mellanby's notion that canine hysteria was introduced by feeding growing dogs on agenzized flour (Dec. 14, 1946, p. 885) cannot be reconciled with experience of the behaviour of healthy dogs or the pathology of those diseased dogs which exhibit canine hysteria. It is very difficult to assess Sir Edward's data, since he omitted to correlate his clinical observations with the ante- and post-mortem pathology of his laboratory dogs and rats. Moreover, his statement that fits were observed in the animals receiving treated [agenzized] flour and were never seen in those having untreated flour was falsified by his earlier statement that fits could often be produced by feeding agenzized flour [my italics]. It would seem that some of the dogs which were fed on agenzized flour did not show fits, but I cannot find any description of them; they are not illustrated in Sir Edward's three tables, they obtained even less notice than the rats which were uniformly negative. This evidence should have been detailed, for it is consistent with the anomalies of naturally occurring canine hysteria of which I will cite two examples from my records.

(1) No further fits have been observed in the dogs whose diet has been changed from biscuit to meat, whereas fits have persisted in some of the dogs whose diet (biscuit) has been maintained. Some have been misled by this phenomenon into attributing the cause of canine hysteria to certain dog biscuits. But I have noted canine hysteria in dogs which since weaning had been fed exclusively on meat. (2) No further fits have been observed in dogs from which roundworms have been expelled, whereas fits have persisted in some of the untreated dogs, although no change has been made in the diet. Many have been influenced by this phenomenon into attributing canine hysteria solely to roundworms. A full understanding of the clinical phenomena the pathology can be fully studied.

My observations of naturally occurring canine hysteria have been incorporated in papers on the B.H.S. infection which is a fully adopted abbreviation for the infection by various well-defined groups of the *β* haemolytic streptococcus (Hare and Hare, 1946). Canine hysteria is not a disease entity, but an event which may occur in the course of a particular infection, it is a type of spasmophilia which is expressed by the infection of dogs infected by the B.H.S. and roundworms (*Toxascaris* and *Oxyuris* sp.). The essential pathology of which has been destroyed within 24 hours of showing canine hysteria is that of the B.H.S. infection plus the

presence of a variable number of roundworms in the duodenum—i.e., chronic tonsillitis, hyperplasia of the reticulo-endothelial system, catarrh of the pylorus of the stomach and duodenum, albuminous degeneration of the liver and kidneys, and, as first recorded by the late Prof. John Evre (1928), toxic encephalopathy.

In my cases I have not observed 'loss of consciousness' and 'epileptiform convulsions,' which Sir Edward reported in some of his dogs. The label 'epileptiform convulsions' (without loss of consciousness) was applied by nineteenth-century French and British veterinary authors to what is now termed canine hysteria. More recent work on the pathology has clarified the differential diagnosis of at least four distinct types of spasmophilia of dogs, one of these types being epileptiform convulsions which are now recognized as due to the B.H.S. infection complicated by coccidiosis. Unfortunately some authors carelessly apply the word 'epileptiform convulsions' (with loss of consciousness) to the behaviour of dogs which are in the condition of hepatic and renal failure. This is the pathology of the terminal stage of several diseases, one of which is the conjoint B.H.S. and roundworm infections.

From Sir Edward's statement that "a time may come, however, when a dog which seems to be acquiring immunity suddenly suffers the most severe epileptiform fits and dies" I infer that his dogs, to which he attributed "epileptiform convulsions" and 'loss of consciousness,' were in a condition of hepatic and renal failure. Sir Edward's description of his dogs' behaviour, apart from "epileptiform convulsions" and "loss of consciousness," seems to me to be consistent with the symptomatology of naturally occurring canine hysteria, which was described in French and British veterinary literature of over 60 years ago. Sir Edward has been gravely misled into attributing our knowledge of canine hysteria to American sources of the past 30 years.

I find further support for my inference that Sir Edward's dogs were suffering from the B.H.S. and roundworm infections from his description of "the actual observed state of the affected animals" in such phrases as 'the attacks seem to represent temporary exacerbations superimposed on a chronic abnormal condition', "in young puppies the attacks came on insidiously and usually took some weeks to develop", "lactating bitches appear to be particularly prone to hysterical fits". I accept Sir Edward's diagnosis of his dogs' behaviour as canine hysteria, not his startling notion of its aetiology. In my opinion he experimented on diseased dogs and mistook the expressions of their disease for the consequences of his dietary changes—I am, etc.

Arsenical Encephalopathy

SIR—The report of a case of arsenical encephalopathy and its treatment by Drs. G. Hipps and R. Goldberg (March 8, p. 296), calls for some comment. Though a case of this nature may be rare in this country it can by no means be described as 'a rare clinical condition'. Such cases were commonly met with in India Command in the years 1942-5 and a large number of deaths occurred from post-arsenical encephalopathy during that period. The condition was almost exclusively confined to Indian O.R.s, the majority being natives of Southern India. Though the diet of Indian troops varied a good deal in its constituents from that of British O.R.s, the part played by sub-clinical vitamin deficiency or by deficient intake of amino-acids containing the essential -SH grouping could not be determined in these fatal cases.

Though symptomatic treatment of effects due to organo-arsenical intoxication is an important feature in the later stages of the syndrome it is now known that specific treatment of the underlying chemo-pathology at an early stage will produce positive results. Recent work on the toxicity of arsenical compounds when injected into the body confirms the work of Voegtlin and his colleagues (Voegtlin, Dyer, and Leonard, 1923, 1925) who showed that organic compounds of the type RAsAsR were inactive in that form but were oxidized in the body to the form RAsO, and that only when they had undergone this change did they exert their toxic action either on the parasites or the host. They showed further that the

arsenoxide so formed reacted with sulphhydryl groups in the body tissues and in the spirochaetes. Hogan and Eagle (1944) showed that the toxicity of any arsenoxide depends on its constitution and its ability to combine with essential functional groups in vital organs.

Many of the enzymes concerned with carbohydrate metabolism are known to be inhibited by reagents which react with sulphhydryl groups (Cori, 1946), and detailed work on this subject has been carried out by Barron and Singer (1945) using a variety of reagents. Glutathione is one of the most important substances in the body containing the thiol group. It is probable that the vitamin protein enzymes are similarly adversely affected by organo arsenicals, for it is known that arsenic interferes with the conversion in the liver of vitamin B₁ to its co enzyme form. The poisoning action of arsenoxide on glutathione is probably one which involves oxidation of its thiol group to a disulphide, resulting in the production of oxidized glutathione. This in turn will bring about the inactivation of succinic dehydrogenase, and as glutathione acts as a catalyst for glyoxalase, the action of this latter enzyme will be also in abeyance. Damage even more widespread will follow, the presence of the sulphhydryl group in several oxidizing enzymes, as well as in several proteolytic and other enzymes, has been shown to be necessary for their activity (Bersin, 1935, Hellerman, 1937, Barron and Singer, 1945). In view of the fact that oxidizing agents in the cell tend to inhibit the activity of -SH enzymes, it is probable that one of the main functions of glutathione in cellular systems is concerned with the continuous reactivation of the -SH enzymes. Its capacity to bring about such a reactivation through its powerful reducing action has been demonstrated in many experiments.

Once enzymic balance has been upset recovery is very possibly hard to effect, and reactions will proceed in one direction faster than metabolism can control them. Lactic acid synthesis is retarded to such a degree that enzymic control in other directions is affected by the building up of aldehydic compounds. It is postulated that this is due to the inactivation of glyoxalase and succinic dehydrogenase, with a subsequent block in the tricarboxylic acid cycle.

The following chain of events leading to the development of arsenical encephalopathy has been suggested by Lydon: (1) Interference with cellular metabolism. (2) Accumulation of metabolites in CNS cells (which are most sensitive to changes in oxygen tension). (3) Increased retention of fluid by cells, with oedema of tissues. (4) Interference with normal capillary circulation. (5) Congestion and subsequent focal necrosis. The characteristic pathological changes found in fatal cases support this theory.

The immediate treatment of post-arsenical encephalopathy should be one which aims at preventing the establishment of the vicious circle mentioned above and opening the way for the restoration of the metabolic sequence known as the Krebs tricarboxylic acid cycle. While it has been shown that the toxic action of arsenoxide is inhibited by the intravenous administration of reduced glutathione (Voegtlin *et al* 1925), recent studies have proved that the most effective compound in use as an antidote against heavy metal poisoning is 2,3 dimercaptopropanol (BAL), which in dogs is many times more effective than glutathione (Long and Farah, 1946). It is recognized that these compounds exert their maximal therapeutic action when given at the earliest possible opportunity after a diagnosis of organo metallic intoxication has been made. As excess of succinate protects its dehydrogenase from the inhibitory effect of oxidized glutathione, the combination of a succinate and an organic thiol compound given parenterally should in theory, give the maximal therapeutic result if administered immediately arsenical intoxication is suspected.

The practice of using intravenous glucose does not appear to be physiologically sound in view of the fact that a disturbance of carbohydrate metabolism is occurring. Double-strength plasma would seem to be the agent of choice in counteracting cerebral oedema. The use of a compound such as calcium thiosulphate does not present an available thiol radicle but merely introduces sulphur in inorganic form. One of the organic thiol or di-thiol compounds mentioned above will produce a far greater and more rapid therapeutic effect. These compounds are now quite easily obtainable—I am, etc.,

Treatment of Post-operative Pulmonary Atelectasis

SIR,—The annotation on a new treatment for post operative atelectasis (March 22, p 386) prompts me to inform you of a method of dealing with this condition which I have used occasionally during the past two years. The method is to stimulate coughing by the introduction of 1 ml of water by means of a syringe, into the respiratory passages, the need being passed into the trachea at about the level of the first ring—that is, below the cricoid cartilage. This method is intended to supplant bronchoscopic aspiration, which, as observers agree, is the ideal method of treatment, and which should be undertaken as soon as signs of atelectasis appear, but the introduction of water may serve as a simple substitute if the facilities for bronchoscopic aspiration are not available.

The last case which I dealt with by this means was a man of 44 who had had a Polya gastrectomy for duodenal ulcer on March 4, 1947. When I visited him on the evening of March 4 he had an atelectasis of the left lower lobe. The surgeon who had operated on the case had left instructions that he was not to be disturbed, and, as he was not to be found, I decided to employ the water technique, though I should have preferred to use the bronchoscope. The effect was excellent: after a violent spasm of coughing, in which considerable sputum was brought up, he stated that he felt better, and his dyspnoea disappeared at once. He continued to bring up sputum for a few days, but all signs of atelectasis had gone, and the temperature, which had been raised on the evening of March 4, became and remained normal.

The birth of this method occurred when I was anaesthetist to a surgical team for chest surgery in the B.L.A., the surgeon in charge being Major J Leigh Collis, of Birmingham. A patient was brought in with collapse of the right lower lobe, the cause being a piece of tinned bacon which he had inhaled. I anaesthetized the patient for bronchoscopy by swabbing the pyriform fossae with 15% cocaine, and then introduced 1 ml of the same fluid into the trachea through the top ring. The patient immediately coughed and expelled the greater part of the inhaled bacon. This suggested to Major Collis and myself the method of causing expulsive coughing which I have described above.

I am tempted to make two comments on Grandstaff's work to which your annotation was directed. First, although I have not seen the original article, I find great difficulty in believing that of a total of 2.6% of respiratory complications following operation (an extremely low figure), two thirds be pneumonia. My own experience, in common with everyone else whom I have consulted, shows that atelectasis is by far the commonest of major respiratory post-operative complications, and that the pneumonia rate is only a very small fraction of this. Secondly, while not denying the possibility remote though it appears to be, that analgesia of the larynx may cause dilatation of the bronchi, it would hardly appear that this of itself would cure atelectasis. It is also necessary that the offending plug be removed, either by aspiration or by coughing. With all due deference to the author of your annotation, swabbing of the pyriform fossae does not "inevitably produce severe coughing", in fact, it practically never does. For this reason Grandstaff's method might well be improved by stimulation of coughing by some such means. I suggest

While on the subject, I should like to mention a point of diagnosis which I have never seen in print. The dyspnoea of atelectasis is always more severe than the physical signs, and it appears to warrant, and the sudden onset of severe dyspnoea after operation is strong presumptive evidence of atelectasis.

It is a very encouraging sign that attention is now being directed to the diagnosis and treatment of post operative atelectasis. Lives have been saved, and many days of convalescence averted, by the prompt use of the method. It is most necessary that all anaesthetists should become conversant in the use of this instrument, and also expert diagnosticians in thoracic disease. Too often, even now, surgeons are content to classify all cases of atelectasis, bronchitis, pneumonia, what have you as "anaesthetic chests" and to bother no more about them.

In conclusion, while stressing the need for early bronchoscopic aspiration, let it not be forgotten that postural coughing

PROLONGED CONTACT
antiseptic

During a systematic investigation into the antibacterial activity of the monoaminoacridines, 5-aminoacridine emerged as an antiseptic having properties similar to those of proflavine. 'Flavogel' (5-aminoacridine) is the Glaxo preparation of this potent antiseptic in a water-miscible jelly base for use on cuts, wounds and protective dressings, etc. 'Flavogel' is valuable also as an antiseptic lubricant for catheters, cystoscopes, and specula, and in ante-natal examinations. 'Flavogel' has a powerful antibacterial activity, is effective in the presence of serum and is prolonged in action. The consistency of the jelly base maintains the antiseptic in contact with the tissues enabling it to exert the maximum antibacterial effect. 'Flavogel' is ready for application direct from the tube. It is convenient to carry, clean to use and does not stain skin or clothing.

Acramine* (5-Aminoacridine) is available also as a powder for making up solutions

FLAVOGEL

5-Aminoacridine Hydrochloride in water soluble jelly base 1-oz. tubes and 9-oz. jars

Vitamin Therapy - its uses and limitations

HABITUAL CONSTIPATION

As early as 1932, work in our laboratories showed the existence of degeneration in the cells of Auerbach's plexus in chronic vitamin B₁ deficiency. Among the developments of recent years is the belief that inositol, another factor of the B complex exerts a stimulating effect upon the gastric and intestinal mobility.

Bemax, containing both these factors in the amounts shown below, but free from coarse fibrous matter, has been found of benefit in correcting habitual constipation.

Vitamin B₁ 0.45 mg per ounce
Inositol approximately 7 mg per ounce

BEMAX *The stabilised embryo of selected cereals*

1 oz. of Bemax also provides approximately —

Vitamin B ₁ (Riboflavin) 0.3 mg	Vitamin E 80 mg	Available Carbohydrate 39.0
Nicotinic Acid 1.7 mg	Manganese 4.0 mg	Fibre 2.0
Vitamin B ₂ 0.45 mg	Iron 2.7 mg	Caloric Value 104
	Copper 0.45 mg	
	Protein 30%

BELLADENAL

Antispasmodic .. Anticonvulsive
.. Sedative ..

BELLADENAL combines the central sedative action of phenobarbitone with the peripheral antispasmodic action of the total levorotatory alkaloids (Bellafoline) of Belladonna leaves. Bellafoline is only half as toxic as atropine in doses which are therapeutically equivalent in their effect on the parasympathetic.

Each tablet of Belladenal contains
Bellafoline 0.00025 Gm (1/250 grain)
Phenobarbitone 0.05 Gm (3/4 grain)

The components of Belladenal act synergistically with each other so that a powerful antispasmodic and sedative effect is obtained with comparatively small doses.

M H ARMSTRONG DAVISON

Penicillin for Breast Abscess

SIR,—A recent article by Florey, MacVine, and Bigby (Dec 7, 1946 p 845) stimulates me to present the results of series of cases treated by one method which they employed—namely, aspiration of the abscess and injection of penicillin solution into the cavity. The technique employed was essentially similar to that which they advocate. The cases referred to presented themselves mainly in the spring of 1946, when the shortage of beds was extremely acute. Previous work on the value of penicillin used locally in abscess cavities of various types, both acute and chronic infected with the staphylococcus and particularly the occasional reports of breast abscess treated by such methods, suggested that these cases might respond to local penicillin. They were therefore treated as outpatients in the casualty department of the Royal Infirmary, Leicester.

The series consisted of 24 cases of whom 15 were primipara and 9 were multipara. Of the latter, two presented with abscesses in both breasts, and four gave a history of mastitis in a previous pregnancy, including both the bilateral cases. About one third of the mothers had not persisted with breast feeding for more than a few days, and subsequently had not regularly emptied the breasts.

The abscesses were first seen in various stages of suppuration from early localization to obvious fluctuation. All cases were treated as follows. Aspiration of the abscess was carried out using a wide bore needle and with full sterile precautions. Pus was found in every case. The pus was replaced with calcium penicillin in normal saline in amounts varying from 50,000 to 200,000 units through the series. A light general anaesthetic was employed with very nervous patients. Cultures of the pus were made in each case and all yielded penicillin-sensitive *Staph aureus*. The procedure was repeated in 24 hours in all cases. In 19 cases, including one bilateral relief from pain was considerable within the first 24 hours of treatment. In the remaining five cases the abscesses remained large, and further daily aspirations up to the fifth day were made. These were all late cases when first seen, with well established cavities. Two eventually healed after discharging freely from the sinuses which had formed along the needle tracks. The remaining three required incision and drainage.

Of the 19 cases which cleared up satisfactorily, 2 relapsed, one after 10 days and the other after 16. Both were given two further aspirations and injections of 100,000 units of penicillin, after which they healed with no further trouble. *Staph aureus* was again grown from both.

All the cases in the series were given a routine course of 30 mg of stilboestrol spread over five days and the normal breast was manually expressed until the flow ceased. In the 19 cases which responded well the total duration of treatment until complete recovery was approximately two weeks, although in some cases a firm painless nodule could be felt up to the fourth and fifth week. The quantity of penicillin injected appeared not to affect the recovery time to any marked extent. In about half the cases particularly those from which fairly large quantities (more than 5 ml) of pus were aspirated, sinuses formed along the needle track and pus discharged freely. All dressings were therefore performed with a completely sterile technique.

(1) The series is too small for generalization, but it seems clear that in cases seen early in the stage of localization, when the volume of the abscess is small, this method of treatment is a satisfactory one and an improvement on surgical methods, however in late cases where large cavities are present it would appear not to be efficacious except as an adjunct to incision and drainage. In this case the intramuscular route is probably the best method of administering the penicillin.

(2) These cases can often be treated in a satisfactory manner as outpatients without surgery, particularly in view of the present bed shortage.

(3) Inquiries among several practitioners in the district suggest that the aetiology of many cases in an industrial town such as this is closely connected with the fact that many women resume work shortly after the puerperium and find it inconvenient or impossible to continue breast feeding. They do not, however empty the breasts adequately and stagnation of milk occurs.

I am indebted to Mr Rizelle the surgeon in charge of the casualty department for permission to publish this article and for his advice at all times—I am, etc.,

West Drayton, Middlesex.

S J KRISTER

Co-opted Members on Negotiating Committee

SIR,—It may not be obvious to everyone that the subcommittees of the Negotiating Committee contain the names of many co-opted members, but it is a fact which, I think, needs definite stressing. It is no doubt necessary to adopt this procedure in order that each particular division of practice should receive the fullest consideration in relation to the Act.

In view of the amount of careful thought time, and trouble which have been bestowed on the negotiation and election of the Negotiating Committee it is to be hoped that the votes of such co-opted members will in no case outweigh those of the elected members, especially when one remembers that the report of the Negotiating Committee on a previous occasion was in fact the report of a small subcommittee which was put quite formally and without the opportunity for discussion, to the full Negotiating Committee before being considered by the Council—I am, etc.,

Hungerford Berks.

D H STUART BOYD

National Health Service Act

SIR,—Dr D G ff Edward (March 15, p 352) contends that we ought not as a profession to oppose the new medical service Act because to do so is undemocratic. May I try to expose the fallacy of such argument? Many besides him are bemused by it nowadays. In fact the general cry is for democracy as the universal cure-all.

A little reflection will show that a whole-hog version of it can never achieve real efficiency in government for the simple reason that its actions can only be the resultants of the more or less fused ideas of every individual on the electoral roll. Some may be very well informed and well balanced while others will be comparatively ignorant or stupid or both. Efficiency under the democratic system is only to be achieved when people will curb themselves and refrain from interfering in matters they do not understand. On the other hand, those who do understand should assert themselves and explain to persuade and be prepared to lead their fellows. That is what our position should be. The general mass of the people is as profoundly ignorant of the working of our profession as it is of the science and art of medicine. If we keep silence we let the whole affair go by default, for we have abundant evidence that the Government itself is little if any better informed in this business than the 'man in the street'.

Anyone desiring to study this matter further will do well to read *The Limits of Pure Democracy* by W H Mallock, Chapman and Hall, 1918—a veritable mine of information and sound thought—I am, etc.

Doncaster

W REGINALD WILSON

Trichlorethylene in Midwifery

SIR,—Perhaps some of those who have inquired about the use of trichlorethylene in midwifery might care to try the simple, cheap apparatus which I described in 1944 in the *Journal of Obstetrics and Gynaecology*.

The first apparatus was improvised in a few minutes and could be again by anyone wishing to try the method. The concertina rubber tube is disconnected from a standard Boyle's gas-oxygen machine, complete with face-piece and three-way gas-cock. The free end of the tube fits nicely over one neck of a 16 oz (450 ml) Woulfe's bottle. A piece of standard rubber drainage tube is inserted into the other neck of the bottle so as to fit closely and reach to within about two inches of the bottom. It is then cut off flush with the neck, the natural curve of the tubing being allowed to direct it to the centre. The mask must be of the inflatable rim type and in good condition. In the absence of positive pressure from gas cylinders, etc., the

amount of the drug inspired depends entirely upon the gas-tight fit of the mask. One ounce (28.4 ml) of trichlorethylene poured into the bottle makes the apparatus ready for use. The three-way tap is kept permanently in the "valves" position so that the patient inspires over the trile and expires into the air. To make the apparatus more foolproof, so that the analgesia can be self-administered, a special gas cock, made for me by A. Charles King, Ltd., can be used. With this the tap position cannot be varied and the valves are of a special low-inertia type.

The cost of the apparatus, using new parts throughout, was about 50s in 1944, which is 'udicrously low compared with that of any other machine. In addition to the above a small wooden box, in which to stand the Woulfe's bottle to prevent its being knocked over, can be used if desired. The diagram will perhaps eke out the deficiencies of the description—I am, etc.,

Stockport Cheshire.

Calvert Walter (1944) *J Obstet Gynaec Brit Emp* 51 140

Shortage of Nurses

SIR—There has been a great deal of prominence given recently to the shortage of nurses, which, as Dr Leonard Ley says (March 15, p 355), is already serious. I have not so far seen any helpful constructive suggestions from the General Nursing Council itself. In this profession good pay, food, and accommodation are not *all* that is necessary to attract younger men and women. Happiness, peace of mind and interest in one's work are far more valuable to the individual than "good hours of work."

I think a great many suitable, capable, practical nurses are lost to the profession on account of the excessive amount of book work and lectures—often far too advanced and detailed for the needs of a good practical nurse. How often do the lectures and tutorials interfere with the continuity of their ward duties and so damp their interest? These young keen recruits are given lectures on all sorts of quite new subjects and have to copy out their lectures afterwards in their "spare" time. These lectures may then be "corrected" by the sister tutors—surely a very boring process for both parties. Far better give them questions to answer on paper if they must have 'home work' and let the sister tutor correct these. The introduction to the theory of nursing is far too rapid and too short, and I think the suggestions in the last two paragraphs of Dr Ley's letter are suggestions on the right lines.

There seems to be a lack of appreciation on the part of the General Nursing Council of the fact that recruits in former days were mostly from the 20–30 year-old group, whereas now they range from 17 years upwards. What is the use of trying to teach these young people about the circle of Willis, the functions of the pituitary and suprarenal glands and the endocrine secretions, the sympathetic nervous system, or about cisterns, traps, drains, water standards of purity for domestic use, and "parasites" (just as a whole—no detail in the syllabus) all of which are included in the General Nursing Council syllabus?

A great opportunity was lost during the war by not giving those women who were "directed" into or chose nursing in preference to the Services the opportunity of learning more about nursing proper. A question to all those who were directed into nursing duties during the war should prove helpful and enlightening to those who are worried and puzzled by the position. As I have written elsewhere on a previous occasion the questions must be searching for the truth and should include such questions as: Why did you prefer nursing to the Services? How much actual nursing did you do and over how many years? Were you asked if you would like to become a trained nurse or were you offered any suggestion that you should sit the preliminary examination? Would you still take up nursing if you were allowed a year or more off the training period on account of your war service? What suggestions would you make to attract more recruits to the nursing profession? Surely such a questionnaire if properly analysed would provide ideas for the better recruitment of nurses—I am etc.

Aberdeen

W M GRAY

Obituary

SIR JOSEPH BARCROFT, CBE, FRS

Sir Joseph Barcroft died suddenly at Cambridge on March 21 at the age of 74. He was one of the great figures in British physiology. His classical researches were on the respiratory function of the blood, and in the course of his investigations he devised among other instruments, the Barcroft apparatus, a differential manometer for measuring gases in small samples of blood. His work in this field is familiar to every medical student. Sir Joseph Barcroft was professor of physiology at Cambridge from 1926 to 1937. After his retirement he began a new career of research in animal biology, to which he contributed almost as much as to human physiology.

Joseph Barcroft was born on July 26, 1872, a son of the late Henry Barcroft, of Newry, Co. Down. He was educated at Bootham's School, York, and at the Leys School, Cambridge, before entering King's College, Cambridge, where he was a prizeman and exhibitor in 1894. He took a first in both parts of the Natural Science Tripos and graduated in 1896. He was awarded the Gedge Prize in 1900, the year in which he was elected FRS, and only shortly after his election to a fellowship at his college. While reader in physiology in the university he soon became known as an able lecturer and research worker. He was Oliver Sharpey lecturer at the Royal College of Physicians in 1915 at a time when his war work was fast making him one of the leading authorities on defence against gas. He was president of the physiological section of the British Association in 1920 and Fullerton Professor at the Royal Institution from 1923 to 1926. Whereas his work before the war had been mainly concerned with the action of haemoglobin as a carrier of oxygen, his interest now shifted to various problems of blood flow and respiration. Later still he worked on the physiology of the nervous system as controlling respiratory movement.

In 1925 Barcroft, on the death of Langley, succeeded to the chair of physiology in Cambridge. Throughout an active life he played a prominent part in maintaining the high tradition of the Cambridge School of Physiology. As head of a large laboratory he found time to take a lively interest in many different investigations, without actively interfering with the natural development of the ideas of his colleagues. His own contributions were many, but perhaps his greatest influence on physiology was through his encouragement of the work of younger men. His enthusiasm, his good humour, his attractive style of writing and speaking and his unusual gift for putting the complicated results of profound thought into the simplest possible language inspired many with a love of his special subject. Though he was not a medical man much of Barcroft's work was with human subjects and much of it a dramatic quality that excited interest in other than academic circles. Thus for many years he represented Cambridge Oxford in favour of the view that the passage of gases through the epithelium of the alveoli of the lungs was a simple physical process and that even under adverse conditions the lungs not take up oxygen unless the oxygen pressure in the air greater than that in the blood. In the course of his work on this subject he led an expedition up the Andes at one time and on another occasion he exposed himself to low oxygen pressure for several days in a glass box in his Cambridge laboratory.

He was knighted in 1935 and in 1937 he was succeeded by Prof E D Adrian. At this point in his life he had already received marks of distinction from many foreign societies.

W. L. G. G. G.

He had been a member of the chemical warfare committee at the War Office and had been made a CBE in 1918. He had honorary degrees from half a dozen universities and he might well have rested on his undoubted laurels. Instead he applied to animal biology all the vigour, skill, and enthusiasm which had formerly been directed to the problems of human physiology. Fundamental research on the large domesticated animals had been somewhat neglected in this country, and it was in 1941, at the age of 69, that he became Director of a new Unit of Animal Physiology for the Agricultural Research Council. He introduced new techniques for watching developing embryos, and he took up an old problem in a new guise—that of the oxygen supply to the foetus *in utero*. Soon a stream of interesting results and papers began to come from his unit. The first volume of his *Researches on Pre-natal Life* has only recently been published and is perhaps the first book of its kind. It deals with the development of function in the progress of foetal life and describes for the most part investigations made in the schools of physiology and agriculture in Cambridge either by Barcroft or by his colleagues and pupils. Most of this work was done upon foetal sheep. There is a comparison between placental and foetal growth in the sheep. There are experiments showing the variation in fats and sugars as between the maternal and foetal blood. There are chapters on growth, and on the relation between maternal nutrition and foetal development. Numerous experiments are described on the transfer of blood from the placenta to the foetus at birth. Like his earlier books, this last contribution bears witness to the breadth of his interests and to his experimental ingenuity. In the midst of all this work he found time to test Anderson shelters on the range at Woolwich and to experiment with dehydrated meat.

Barcroft's teaching, like his research, made no parade of learning. In the physiological laboratory at Cambridge he was always ready to help an undergraduate with the most elementary experiment and with a simple friendliness that immediately put the student at his ease. In 1943 he received the Copley Medal, the highest award which the Royal Society can give. During his 74 years of active life there were few honours which had not come his way. But physiologists all over the world will remember him as "J.B.," a worthy successor to Michael Foster and Langley.

Prof Thomas Nicol writes: Dr R. J. GLADSTONE was a much loved and respected member of the Anatomical Society and will be greatly missed by his many admirers and friends. Especially do we feel his passing a personal loss at King's College, London where he had worked since 1912. Even during his retirement he remained attached to the anatomy department and produced a beautiful series of illustrated sections of embryos, which is of great value for teaching and research. This work was completed only just before his death. His wide knowledge of biology and comparative anatomy, his great artistic gifts and his constant thirst for further information resulted in many contributions to anatomical knowledge, and these are especially valuable because of his critical judgment. He was always a champion of the young man and there are many who will for ever owe him a great debt. His willingness to help others was one of his outstanding qualities. We extend to his widow and family our deepest sympathy in their irreparable loss.

Dr RICHARD RICE died at his home in Harwell, Berkshire, on March 7 aged 88. He qualified at Charing Cross Hospital in 1879 and was in general practice until January 1945. He married in 1885 Helen, daughter of the late Col W. A. Ross of the Bengal Artillery, and is survived by four of his seven children. He had been a member of the British Medical Association for over sixty years.

A. A. B. writes: Richard Rice possessed a radiantly healthy mind and body. For sixty-two years he practised at Harwell, giving unstinted service to the people in the surrounding countryside. His powerful personality combined with a deep understanding of men and women, his industry and sustained professional skill had made him loved and respected by thousands. For many years there was no other doctor within a radius of seven miles and so an eminently sound clinician soon became an outstanding practitioner and obstetrician. During his whole career he seldom took a holiday. He was an energetic and faithful churchman and a churchwarden of the parish church for over half a century. He sang in the choir until he retired from practice, and for many years was

choirmaster. There were few positions of trust locally which he had not held at some time. For years he hunted twice a week during the season. An endearing side of his character was his championship of the young in any discussion, and his enduring love for small children. To accompany him on a long country round into the downland villages was an unforgettable experience. The bare bones of general practice became miraculously clothed as he recounted incidents of vivid interest from the past.

Dr Margaret L. Weir writes: It was with a feeling of great personal loss that I heard of the death of Dr Richard Rice. I had the privilege of being his first assistant and partner. Dr Rice was a clinician of the highest order and a man of unflinching integrity. He combined professional skill with a clear, sympathetic understanding of his patients and gave himself unsparingly to the service of all classes of the community, who in return gave him their deepest trust and love. As a family doctor he had an extensive maternity practice, and in this particular branch he will be long remembered for his high professional ability, kindness and infinite patience. During his few hours of leisure he read extensively, taking a keen interest in every new development of medical science. He was a great lover of Nature, and got much happiness and peace in his garden among his roses.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

The following degrees were conferred on March 15

MD—*F. S. Maclean J. W. Crofton
M. Chir.—A. S. Till
M. B. B. Chir.—*W. B. Webb

UNIVERSITY OF LONDON

Edward Tenney Casswell Spooner, M.D., has been appointed to the University Chair of Bacteriology and Immunology tenable at the London School of Hygiene and Tropical Medicine from Oct. 1.

Robert Henry Stewart Thompson, D.M., has been appointed to the University Chair of Chemical Pathology tenable at Guy's Hospital Medical School from Oct. 1.

Hans Gruneberg, M.D., has been appointed to the University Readership in Genetics tenable at University College from Oct. 1, 1946.

UNIVERSITY OF LONDON

Alan Kekwick, M.B., B. Chir., M.R.C.P., has been appointed to the Chair of Medicine tenable at the Middlesex Hospital and Medical School from Oct. 1, 1946.

UNIVERSITY OF LIVERPOOL

The following candidates have been approved at the examinations indicated

MD—Anne E. McCandless, H. Peaston, T. G. Richards, A. G. Rickards, M. B. Ch.B.—13J. C. Davis, 12J. Janet H. Mountford, 13H. H. Whincup
FINAL M.B. Ch.B.—Part III—Olive M. Bell, J. H. Brenner, G. B. Brown, Mary E. Casper, Beryl G. Castell, J. B. Cowie, W. M. Edwards, Jeanne A. Elphick, D. W. A. Evans, A. J. Farmer, I. L. Francis, H. J. Gilbride, T. H. H. Green, P. Hampson, M. F. Holt, Joan M. Hughes, E. Jones, Meira Jones, S. Kalinsky, H. Keidan, F. D. Kitchen, Edith G. Mercer, Alicia J. Middle, J. Moloney, Dorothy M. Morris, Jones, J. M. Old, W. L. Owen, Dorothy C. Peterson, Helen Poole, J. S. Porterfield, J. K. M. Rawlinson, Elizabeth Rhind, L. Robinson, D. L. Sharples, K. S. Shaw, W. B. Smellie, R. J. Smith, Elizabeth Taylor, W. A. L. Thompson, B. Towers, Pamela J. Tyson, D. G. Walker, Barbara M. Webber, D. J. West, D. P. C. Williams, Jessie I. Young.
Medicine and Obstetrics and Gynaecology—F. G. Anderson, I. S. J. Crosbie, Elizabeth Howarth, J. E. Ridine, Audrey A. Shone, M. H. Turner, Medicine and Surgery—E. Dewsbury, Nancy V. Dilling, Sheila K. Frazer, A. B. Jones, F. P. Lennon, G. C. Snee, L. C. Wolfman, Surgery and Obstetrics and Gynaecology—W. Ellenbogen, G. I. T. Griffiths, G. L. Levy, G. H. Lucas.
DPM—Part I—A. R. Unsworth, P. Weyman.
CERTIFICATE IN PUBLIC HEALTH—G. Davies, Barbara W. Gerrard.
1 With second-class honours. 2 Distinction in surgery. 3 Distinction in obstetrics and gynaecology.

UNIVERSITY OF MANCHESTER

At a special meeting of the University Court held on March 21, authority was given for the conferment, on May 21, of the honorary degree of D.Sc. on Prof. Edgar Douglas Adrian, O.M., M.D., F.R.S., F.R.C.P., for contributions to the study of physiology. The following candidates have been approved at the examination indicated.

DPM—Part I—G. Christie, A. Clark, H. A. Cole, R. Cotter, R. C. Cunningham, S. Falk, F. Howarth, I. McD. Kerr, M. G. McColl, R. S. Williams.

UNIVERSITY OF SHEFFIELD

The following appointments were made at a meeting of the University Council held on March 21. Honorary Lecturer in Venereal Diseases—Douglas Ogilvie Stevenson, M.B., Ch.B. Tutor in Child Health—Cynthia Mary Redhead, M.B., B.S. Assistant Tutor in Obstetrics—Samuel James Barr, M.B., Ch.B.

UNIVERSITY OF BIRMINGHAM

Lancelot Hogben, D Sc, FRS, Mason professor of zoology, has been appointed to the Chair of Medical Statistics in the University

UNIVERSITY OF EDINBURGH

The seventh Sharpey Schafer Memorial Lecture will be delivered by Dr Charles H Kellaway, MD, FRS, FRCP, FRACP, director in chief, Wellcome Research Institution, London on Tuesday, April 22, at 5 p.m., in the University New Buildings, Teviot Place, Edinburgh. His subject is "The Perfusion Experiment in the Study of Tissue Injury". All interested are invited to attend the lecture.

UNIVERSITY OF GLASGOW

A series of papers will be read in the Department of Ophthalmology of the University on Wednesdays, at 8 p.m., from April 9 to 30, both dates inclusive. The general arrangements will be similar to those in the series held last year, and the meetings will be open to all medical practitioners and senior students interested in ophthalmology. Details will be published in the diary column of the *Supplement* week by week.

CONJOINT BOARD IN SCOTLAND

Medico-Legal

COCAINE IN MISTAKE FOR PROCAINE

The danger of prescribing by telephone was again grimly illustrated at a recent action in the High Court before Mr Justice Hilbery. A patient undergoing a jaw operation at Wellhouse Hospital, Barnet, died after an injection of 80 ml of 1% cocaine solution with 1/20,000 adrenaline. His widow sued the Hertfordshire County Council and Mr Alan Henderson Hunt, the surgeon, for damages.

Mr Hunt said in evidence that on the day before the operation he telephoned instructions to Dr Eleanor Knight, who was not then qualified but was acting as student-house surgeon, to have ready 100 ml of 1% procaine and 1/200,000 adrenaline, adding that the dose of the latter was about 5 minims (0.3 ml). He always, he said, used the name procaine, "novocain" was a German trade name and since the war its use had been discouraged. No prescription was needed for the solution he had ordered, and Miss Knight ought to have known that the cocaine solution was lethal. He also maintained that the pharmacist should, before dispensing the solution, have obtained written instructions and the signature of a qualified person, or have queried the verbal instructions.

The learned judge, after a hearing lasting four and a half days, found that Mr Hunt, Dr Knight, and the pharmacist had been negligent. Although, he said, Mr Hunt expected Dr Knight to use her skill and reason and to bring her mind to bear on what he was saying, he was still under a duty to ensure that he was getting what he ordered. Dr Knight was negligent because she knew the solution was lethal and required for an injection. The pharmacist was at fault for accepting an order by word of mouth for an unheard of dosage for injection of cocaine and adrenaline, and for taking no steps whatever to insist upon a qualified person initialling the order. He had made no attempt to check with Mr Hunt, and had disregarded every sort of ordinary safeguard in the making-up of dangerous drugs, together with the instruction in the *British Pharmacopoeia* that a pharmacist, when required to dispense an unusually large quantity of a dangerous drug should take steps to verify. The hospital was responsible for the negligence of Dr Knight (not then qualified) and of the pharmacist but not for that of Mr Hunt. In addition, it had permitted the use of a dangerous and negligent system under which a pharmacist was able on a verbal order to dispense a phenomenal amount of a dangerous drug without a qualified person's signature and had failed to bring to Dr Knight's attention the rules concerning dangerous drugs. He awarded £2,500 damages and costs, to be shared equally between Mr Hunt and the hospital.

Medical News

Clinico-pathological demonstrations will be given in the Meystein Lecture Theatre of Westminster Hospital School of Medicine (Horseferry Road, S.W.) on Monday, April 14, at 5 p.m., when two cases of hypertension, (1) peri arteritis nodosa and (2) tumour of adrenal, will be shown.

A meeting of the Eugenics Society will be held at the Royal Society's rooms (Burlington House, Piccadilly, W.) on Tuesday, April 15, at 5.30 p.m., when Dr Linford Rees will speak on "The Physical Constitution in Mental Illness". All interested in the subject are invited to attend the meeting.

Lord Rothschild will deliver the annual oration on "The Problem of Fertilization" before the London Jewish Hospital Medical Society at the West London Synagogue, Seymour Place, W., on Thursday, April 17, at 8 p.m.

A general meeting of the Heberden Society will be held at 11 Chandos Street, London, W., on Friday, April 18, at 5 p.m., when Dr Graham Weddell will deliver an address on "The Structure of Striated Muscle in Relation to its Function". A discussion will follow.

A two day conference, intended mainly for teachers and well-workers but open to the general public, on "Education for Family Life" will be held in Manchester on April 21-22 by the Extra Mural Department of the University of Manchester assisted by the British Social Hygiene Council. Lectures will be given by Dr Ethel Duffin, Mr Cyril Bibby, Mr R. Weatherall, and others. The fee for the course will be 5s. Particulars are obtainable from the Director of Extra Mural Studies, the University, Manchester, 13, or from the Secretary, British Social Hygiene Council, Tavistock House North, Tavistock Square, London, W.C.1.

The Royal Free Hospital Old Students' Association reunion dinner will be held at the Café Royal, Regent Street, London, W., on Wednesday, April 30. Tickets 25s (wines exclusive) may be had on application to either of the honorary secretaries of the association, Dr Barbara Mitchell (6, Church Street Epsom) or Mr Jocelyn Moore, F.R.C.S. (4, Devonshire Place W.1).

The New York Academy of Medicine has attained its 100th anniversary and is celebrating the occasion with a series of lectures and discussions in March and April. It has also issued a small illustrated pamphlet outlining the history of the Academy. The Academy was founded on Jan. 6, 1847, "to foster the best ethical relation between the profession and the public and within the profession itself for the continued education of the physician and for the encouragement and promotion of the advancement of the medical science in all its numerous parts and phases". The Academy concerned itself with public health as early as the first year of its life—endorsing a proposed law for the registration of births, deaths, and marriages, demanding legislation to control the import of drugs and urging action for the care of youthful idlers. In the same year, 1847, the Academy appointed a committee to investigate an outbreak of typhus fever and took the unusual step of ordering the report to be printed in the daily Press as well as in medical journals. Not until 30 years after the foundation of the Academy did the library reach any size, but from the small number of 400 volumes in 1875 it rapidly expanded to some 9,000 volumes in 1879, and by 1880 it had acquired 17,000, there are now over 248,000 volumes. The Academy was housed in its present home at 103rd Street and 5th Avenue in 1926.

The Dutch Society of Psychiatry and Neurology will hold an international meeting in Amsterdam from June 13 to 15 to celebrate the 75th anniversary of the Society and several leading psychiatrists and neurologists of England, Switzerland, Belgium and Holland have already promised to read papers. The Dutch hope to have specialists from the United Kingdom, with their wives, at the meeting. Those wishing to be present should communicate with the secretary of the Royal Medico Psychological Association, 11 Chandos Street, London, W.1, by April 15.

Dr William Smith, of London, S.E.3, was elected to the Greenwich Borough Council, South-east Ward at the by-election on March 20. The polling was as follows: Dr Smith Conservative, 2,233; Mr T. Smith, Labour, 976; Mr A. Purvis Liberal. Dr Smith stressed in his election address that local government does not need political parties and that decisions should be reached free of political prejudice.

Under a recommendation of the Wheatley Committee, agreed by the Secretary of State for Scotland, student nurses in general hospitals with a four year training contract who become registered nurses before the end of their contract will, after April, be graded and paid as staff nurses. They will receive a salary of £120 a year with free board, lodging, and laundry.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended March 15

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland
Figures of Births and Deaths and of Deaths recorded under each infectious disease are for (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland
 A dash — denotes no cases a blank space denotes disease not notifiable or no return available

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* a rise occurred in the incidence of scarlet fever 119, acute pneumonia 118 and cerebrospinal fever 21, while a decrease was recorded for measles 868 and whooping-cough 54

A small increase in the notifications of scarlet fever was recorded in most areas, the largest local rise being 35 in London. The increase in cases of pneumonia was fairly general throughout the country and no large rise was recorded in any area.

The only change of any size in the local trends of diphtheria was a decrease of 11 in London. The notifications of cerebrospinal fever were the largest for any week since the beginning of 1943. The cases notified during the week appeared mainly as single cases spread over almost the whole country. The chief centres of infection were Yorkshire West Riding 12, Warwickshire 11, Middlesex 10, London 9, Glamorganshire 8, and Lancashire 6.

The incidence of whooping cough showed considerable fluctuations in the West Midland counties the cases increased by 57, while the largest decreases were Yorkshire West Riding 41 and Essex 32.

The largest falls in the notifications of measles were Lancashire 293, Middlesex 187, and Surrey 104, the largest increases were Glamorganshire 91 and Gloucestershire 85. The chief features of the notifications of dysentery were rises in Middlesex from 12 to 30 (Southall M.B. 23) and in Lancashire from 4 to 16.

In *Scotland* decreases were recorded for dysentery 22 and measles 19 and there were rises in the incidence of diphtheria 20 and scarlet fever 16. The rise in cases of diphtheria and scarlet fever occurred in Glasgow. No further cases of dysentery were reported from the outbreak in Banff county.

In *Eire* the chief feature of the returns was an increase of 84 in the notifications of whooping-cough, a new outbreak was reported from Tipperary, Roscrea No. 1 R.D., involving 81 persons, and there was an increase from 87 to 102 in Dublin C.B.

In *Northern Ireland* the epidemic of measles in Belfast C.B. continued to subside, notifications decreasing from 165 to 99.

Quarterly Returns for Scotland

The birth rate during the December quarter was 22.1 per 1,000 and was the highest rate for any quarter since 1926. The infant mortality rate was 56 per 1,000 registered live births and was the lowest ever recorded for a fourth quarter. The stillbirths were equivalent to a rate of 32 per 1,000 registered births. Maternal mortality was 2.7 per 1,000 live births and was 0.8 below the average of the five preceding fourth quarters. The general death rate was 12.7 per 1,000 being 0.9 below the five years average. The death rate from tuberculosis increased. For all forms of tuberculosis the death rate was 79 per 100,000 and for respiratory tuberculosis it was 66, these rates being 8 and 9 respectively, above the rate for the fourth quarter of 1945 and 5 and 7 above the five years average. There were 148 deaths from the principal epidemic diseases, they included influenza 62, whooping-cough 33, cerebrospinal fever 21, diphtheria 16 and measles 13.

The preliminary statement for 1946 shows an annual birth rate of 20.3 per 1,000. The stillbirth rate was 32. The infant mortality was 54 per 1,000 live births and was the lowest rate ever recorded. The neonatal death rate was 30 per 1,000 and was 1 above the rate for 1945. The general death rate was 13.1 and was the lowest rate since 1939. Deaths from diphtheria numbered 91, the smallest number ever registered in Scotland. The death rate from respiratory tuberculosis was 64 per 1,000 and from all forms of tuberculosis 79. The former rate was 4 above the 1945 rate while the latter was the same. The marriage rate was 8.9 per 1,000 and was 0.4 above the five years average (1941-5) and 1.3 above the pre-war average (1934-8).

* Measles and whooping-cough are not notifiable in Scotland and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county) and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire. Return of births and deaths for Eire for weeks ended March 8 and 15 is not yet available.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Treatment of Infertility

Q—A childless woman aged 38 who has been married for 5 years is desirous of having a family. She is perfectly healthy and after thorough investigation no gynaecological defect has been found. The tubes are patent. A course of gonadotrophin did not produce the desired result. The husband's semen is normal. Can you suggest any treatment?

A—Every case of infertility has a cause—indeed, there are often several causal factors present in any one case. Although it is sometimes difficult to find any abnormality, the number of cases in which the findings are negative depends to a large extent on the completeness of the investigation. It would therefore be desirable to know what is covered by "thorough investigation" and on what evidence the semen is pronounced "normal". Has it been demonstrated that the woman is ovulating, and, if so, how often? If she is ovulating, what was the indication for giving gonadotrophin? Has the penetrability of the cervical mucus to spermatozoa been tested? Unless there is some guide to the cause, treatment must be empirical and the result is not likely to be satisfactory. It might be worth while arranging for the woman to keep a daily record of the vaginal temperature on waking, in order to determine the day on which ovulation occurs and the optimum time for coitus. Empirical lines of treatment which might be considered include tubal insufflations of carbon dioxide or injections of lipiodol immediately after menstruation for a few months, and pre-coital douches of 1% sodium bicarbonate or 1% glucose in Ringer's solution.

Pancreatic Grafts for Diabetes

Q—I was interested in the article (Oct 19 1946 p 570) on the successful treatment of Addison's disease by a graft. Have pancreatic grafts been tried in the treatment of diabetes mellitus? Is the possibility that hypofunction of insulin is due to an overaction of the glycotrophic factor of the anterior pituitary likely to militate against the success of such a graft?

A—A successful pancreatic graft has not hitherto been recorded, though such grafting has been attempted. One of the chief difficulties is that the pancreas is a double gland, of which the acinous portion forms 99/100ths and the islands of Langerhans the remaining 1/100th. Since the acinous portion is not wanted by the diabetic patient this will inevitably degenerate and involve the islet cells in a mass of necrotic tissue. The islands of Langerhans can be destroyed by repeated injection of a crude pituitary extract, but it is believed that this does not occur in 75% of patients with diabetes since the islet cells are apparently healthy when examined immediately after death. It may be an important factor in the remaining 25% of patients, where the β -cells are definitely unhealthy. Therefore a graft should not be injured by the secretion of the pituitary gland in the great majority of cases.

Abdominal "Cramps" and Duodenal Ulcer

Q—Where a diagnosis of duodenal ulcer has been established and the patient complains of severe "cramps" in the stomach can you suggest oral treatment (a) for the immediate relief of the "cramps" and (b) for the ensuing period? Injections are impracticable.

A—Persistent pain of colicky type never occurs as the result of duodenal ulceration unless the condition be complicated either by stenosis or by penetration of the ulcer and adherence to neighbouring structures. In either case surgery is indicated. In the absence of information about length of history, vomiting, relation of pain to food, etc., it is impossible to be precise

about treatment. As a temporary measure ext. hyoscine hq. minims 15 (0.9 ml) four-hourly will probably relieve the pain. This is considerably above the B.P. dose and may soon be reduced, provided dryness of the mouth be maintained.

Inheritance of Deaf-mutism

Q—A young woman is engaged to one of two healthy brothers whose parents were both deaf and dumb. Further details are not known. What are the chances of her children being deaf-mutes?

A—The fact that the deaf-mute parents had two normal children suggests that the deafness in one or both may have been due to a non-genetic cause—for example, meningitis or scarlet fever. Alternatively, as has been sometimes suspected in similar instances, the deafness in the parents may have been due to different recessive genes. It would therefore appear that at the worst the two sons are carriers of the gene, but unless the young woman herself also happens to be a carrier of the same gene all children will be normal. Unless she is a blood relative of the man, or unless she has a history of deaf-mutism in her own family, the chance of her being a carrier is small and so the chance that a child of this marriage will be a congenital deaf-mute should be no more than one in some hundreds. It would be well to point out that there is a greater risk of a deaf-mute's appearing than in a marriage with no history of this kind, because however small a chance may be it will come off occasionally. But it should be emphasized how small the risk appears to be—considerably smaller, in fact, than the risk that any random pregnancy may end in a congenital malformation of some kind or other.

Discharge from the Nipple

Q—A married woman aged 44 who has no children but who has had several miscarriages for six months has noticed a serous discharge from the left nipple sometimes negligible in quantity but at times profuse. There is evidence of mastitis. What is the treatment?

A—A discharge from the nipple is due to irritation of a duct and almost always comes from the same duct. If it is turbid it may be due to changes related to chronic mastitis in which case the treatment is that of the underlying chronic mastitis. If it is blood-stained it is evidence of a papilloma in the duct. In this case the duct may be identified by sealine it with collodion so that it becomes dilated. At operation a strand of silkworm gut may then be passed down the duct, or it may be possible to follow it by its distension and discoloration. If this manoeuvre fails a local amputation of the breast is needed. If the condition is neglected it may become carcinomatous. A clear serous discharge is more likely to be due to papilloma than to chronic mastitis. It is not an urgent indication for operation but should be watched, operation will probably be needed eventually.

Marriage after Tuberculous Peritonitis

Q—A woman of 28 had tuberculous peritonitis of unknown origin twelve months ago. The ascites was drained midway between the umbilicus and pubes. She spent eight months in the sanatorium. Now the temperature and pulse are normal and there is no sign of the disease anywhere. Her nutrition is excellent but the erythrocyte sedimentation rate is slightly raised. She is anxious to know if she is suitable for marriage from the point of view of health and sterility.

A—The patient's physical fitness for marriage depends to a large extent on what will be her living conditions afterwards. If she can continue an easy life there is probably no objection to marriage. If, however, she will be expected to undertake all the household work and to assume the many worries associated with housekeeping then deferment of marriage for at least a further year seems desirable. If she gets married pregnancy should be postponed for not less than two years lest the pregnancy and labour or the added work involved looking after the baby reawake a quiescent lesion. But the question implies it is highly probable that the woman is either sterile because the tubes are likely to have been infected or to have been occluded by peritoneal adhesions. This is

inevitable, however, and could be demonstrated only by some test of tubal patency, salpingography probably being the best. Endometrial biopsy to exclude tuberculous endometritis might also be considered. However, all such procedures are best avoided at this juncture, for they may reactivate the disease, indeed, unless her prospects of marriage are dependent on her fertility, there is much to be said for a policy of non-intervention until the marriage has proved unfruitful. The situation should of course, be explained to the prospective husband.

MCV in Pseudo-aplastic Anaemia

Q—*Damashek and Schwartz (Medicine 1940 19 231) point out that the macrocytic character of haemolytic anaemias is due to the presence of immature but normal erythrocytes in the circulation. Is the same explanation applicable to the high mean corpuscular volume of the erythrocytes in cases of pseudo-aplastic anaemia during a relapse?*

A—Haemolytic anaemias are not necessarily macrocytic, for instance, in familial acholuric jaundice there may be microcytosis. The macrocytosis, if present, is probably due to at least two different factors. The most important is megaloblastic hyperplasia of the bone marrow associated with disorders of liver function, which can be demonstrated by investigation of liver efficiency. The second factor may be the presence of immature but normal erythrocytes. The latter cannot be the cause of a high mean corpuscular volume in cases of pseudo-aplastic anaemia in relapse, since in aplastic anaemia few if any young red cells are found in the peripheral blood. The question is, however, difficult to answer as the criteria for making a diagnosis of pseudo-aplastic anaemia are not given.

Trigeminal Neuralgia

Q—*Is trigeminal neuralgia indicative of a psychogenic disease or merely the natural consequence of a deterioration in the physical condition of the patient? Can a state of complete remission be attained by psychiatric treatment?*

A—Genuine trigeminal neuralgia is not a psychogenic affection, and psychological treatment is not indicated. At the same time this disorder can scarcely be laid at the doors of any "deterioration in the general condition." Aetiology and pathogenesis are admittedly obscure, and the patient may be in good health apart from the presenting symptom—in the early stages at any rate.

Attacks of "Narcolepsy"

Q—*Could you advise me as to the treatment of a lady aged 40 who has had attacks of narcolepsy for the last forty years? She sleeps well at night but continually falls asleep during the day while sitting down. Amphetamine has had no effect. She has no past history of importance but now has a mild generalized arteriosclerosis with some hypertension.*

A—Narcolepsy in a woman of 70 must be a most unusual occurrence and when in addition, the patient is said to be resistant to amphetamine the diagnosis is rendered even more doubtful. Could not the case be one merely of "somnolence" or a cerebral arteriopathy? Another question arises as to whether such a patient actually needs any treatment at all. Other pharmacological means for promoting wakefulness are, of course, ephedrine and also caffeine.

Contraception

Q—*What is the most efficacious means of contraception in a married woman aged 25?*

A—A "Dutch cap" vaginal pessary used in conjunction with chemical contraceptive jelly or soluble pessary is the most satisfactory appliance as a rule. The size of the "Dutch cap" must suit the individual patient and care must be taken to instruct her in its use. The wearing of a condom by the male partner to some extent from the pleasure of coitus and is intensive but it has the great advantage of simplicity and is effective, but not absolutely safe—the choice depends much on the views of the couple concerned.

Letters and Notes

Control of Measles

Dr A CRAWFORD MAYER (Brackley, Northants) writes: From the pen of one of the elder members of our profession, and one so well qualified, we should perhaps expect a more valuable contribution to our fund of medical knowledge than is provided in the short statement by Mr Elwin Harris on the control of measles (March 8, p 323). The articles referred to by Mr Harris recommended the oiling of floors, bed clothes, etc., in an attempt to reduce the bacterial content of the air. Mr Harris apparently wishes us to believe that he achieves that object more simply by oiling the patient, a recommendation which conjures up in my mind the vision of his measles patients lying naked in bed, their well oiled bodies serving as an area of attraction for the bacteria of the sickroom. If on the other hand Mr Harris allows the oiled bodies of his patients to be covered by bed clothes, I cannot understand how the oil can affect the bacterial content of the air. In support of his contention your correspondent remarks that he cannot recall a single case of otitis media complicating measles in his 22 years of general practice. As a scientific observation this statement is, I submit, of doubtful value. In science the verb should be "record," not "recall." In experimental science control cases are necessary. In my 12 years of general practice I also cannot recall a complicating otitis media and yet none of my patients was treated by oiling. Perhaps my cases are the control required to allow us to assess the scientific value of Mr Harris's observations.

Endogenous Depression in General Practice

Dr C A H WATTS (Ibstock, Leicester) writes: I am obliged to Mr H I Deitch and Dr P E F Frossard (Feb 1, p 208) for their information as to how psychiatric cases are dealt with in their parts of Britain. It is gratifying to find that there are more progressive systems than exist in this part of the world. I am in country practice near a large town with a very fine general hospital, but there is no psychiatric department worthy of the name. One day in each fortnight is allotted to country patients. If any case needs treatment he is referred to the local asylum. There is a university centre within forty miles, but again there are no facilities for ECT or specialist treatment. I have found a psychiatrist who will give convulsive therapy privately, but his fees are far beyond any working-class practice. The only place to which I can refer cases is the mental hospital, which has no OP department. I think that to send mild depressives and anxiety states to an asylum is like referring all skin conditions to a Lock Hospital. I agree with Dr A Lionel Rowson (Feb 15, p 271) that it is high time the whole system was revised. Mental hospitals should house only incurables. No case should be referred to such an institution until every available measure has been taken to effect a cure in the psychiatric wing of a general hospital. OP departments in mental hospitals should be encouraged as a temporary measure until general hospitals have facilities and accommodation necessary. Psychiatry is very much the Cinderella of medicine.

Endocrine Receptors

Dr H BAB (London, NW3) writes: The theory of special receptors in tissue cells upon which the effectiveness of hormones depends, established by Mr Aleck Bourne (Jan 18, p 97) is related to the fact sometimes pointed out in the past by various authors that hormone activity may depend on either deficiency of hormones, or inability of a hormone to act upon a particular tissue (e.g., the pituitary thyrotrophic hormone in the exophthalmic ophthalmoplegic group, as discussed by Dr S L Simpson Feb 15, p 270). In 1917 I described nasal bleeding caused by oestrogen from the ovary in cases of amenorrhoea or oligomenorrhoea due to a hypoplastic uterus. Vicarious epistaxis is a substitute for uterine bleeding and a supplement in oligomenorrhoea. Certain chemical substances are capable of acting upon cells only if the cells possess suitable specific receptors. This factor determines the normal metabolism of nutrition and respiration. The same principle may be seen in the ovum that can be fertilized only by spermatozoa of the same or closely related species, in potassium cyanide acting only on certain cells and in penicillin destroying certain micro-organisms and being harmless to others. There is a universal phenomenon, the principle of receptor activity in cell biology.

Bleeding Tooth sockets

Dr JOHN CAMBROOK (London W1) writes: There are certain measures I think should be added to your reply to the above question in the issue of March 8 (p 322). Haemorrhage from tooth sockets arises either from the soft tissues or the bony socket itself. Pressure either side of the socket with the thumb and forefinger

will markedly diminish the flow in the first type. In these cases a stitch passed through the gum either side of the socket and drawn tightly together coupled with biting upon a bolus of cotton wool will usually suffice. Where haemorrhage is from the socket proper, the effect of biting upon a bolus coupled with the use of a four-tailed bandage if necessary should be tried. Where this is unsuccessful a mushroom shaped plug of cotton wool of such a size that the head can amply cover the socket and the stalk $1\frac{1}{4}$ in (0.63 cm) long is prepared. This is soaked in hot snake venom and the stalk placed in the socket so that when pressure is applied the venom mixes with the blood in the socket as it is occluded. Hot venom is used as its coagulative power is greatly increased for a few minutes before it becomes inactive, and it is during the first five minutes that its action is most helpful. When bleeding ceases the plug is left *in situ* so as not to disturb the clot, and it falls away after a few hours. In cases where the socket is already occupied by clot I have been successful in many cases by injecting venom into the socket and then using occlusion to prevent the escape of the mixed venom and blood. In cases where haemorrhage has been persistent the injection of morphine $1\frac{1}{4}$ gr (16 mg) has much to be recommended in calming the patient and lessening the bleeding. Finally, all patients should occupy an upright position, even in bed until all danger of haemorrhage has ceased.

Sulphonamide Snuff for Colds

Dr J F BUCKMASTER (Berkhamsted) writes. The reply to a question about sulphonamide snuff for colds (March 8, p. 322) suggests that the writer has had little practical experience of the use of sulphathiazole (with or without penicillin) in the common cold. Since Delafield, Straker, and Topley wrote their paper in the *British Medical Journal* 1941, 1 145, six papers have been published describing over 700 treatments with antiseptic snuffs. Dr Kenneth Hazell and myself did a large scale experiment and satisfied ourselves and our patients that the powder spray method materially shortened and mitigated the common cold by reducing the secondary bacterial invasion. In our experiment a total of 2 g. of snuff was given over a three day period (some patients needed a little more for an extra 2 days). It is unlikely that any toxicity could arise even if the snuff were taken continuously for three weeks. Further, it is unusual for an adult to swallow mucus, and if the writer would try the experiment he would find that most of the snuff is blown out on the handkerchief. He would also find that the snuff so reduced the secretion that the necessity for blowing the nose arose only four or five times a day in the acute stage. He might even notice that congress with his fellows was less onerous and that at night a clear nasal airway was of some benefit, even if he slept alone. In the 1st sentence of the answer the writer suggests (perhaps unwittingly) that the snuffs are of some value in the secondary bacterial invasion of the common cold. In this I agree. Perhaps he would try some sulphathiazole and penicillin. It is a harmless procedure.

Intravenous Procaine

Dr E FALKNER HILL (Manchester) writes. In answer to the question "What is the action of novocain (procaine) when given intravenously?" (Feb 15, p. 282) your correspondent says, "There are no records of a suitable dose for intravenous injection." In *Curr Res Anaesth* (1946, 25, 1) he will find a paper in which a number of cases are described and the dose given in each case. Some 15 years ago I had occasion to inject 0.3 g. of procaine intravenously in the course of 10 minutes. There appeared to be neither sign nor symptom as a result. The B.P. and respiration were unaffected, and the patient made no complaint of dizziness or other subjective sensation. As regards animals an experiment in which 75 mg. was injected each minute into the jugular vein of a cat needed 24 minutes before paralysis of respiration occurred and then 2 minutes' artificial respiration was sufficient to enable the cat to carry on by itself. 0.18 g. for a cat is about equivalent to ten times the maximum dose of novocain used in clinical spinal anaesthesia. Procaine has been suggested as a suitable anaesthetic given intravenously for obstetric cases.

Testimonials for Released M.O.s

The Director General of Medical Services (Air Ministry, London) writes. The assistance of your *Journal* would be appreciated in clearing up a misunderstanding among released medical officers regarding the furnishing of testimonials by this Directorate General. A document of this nature if it is to be of any value must be written by someone who has a personal knowledge of the individual who requests it, and on this condition senior officers are empowered to give such testimonials. The practice in this Directorate General is to advise ex-Service doctors who write to us for testimonials to apply to senior officers of the medical branch under whom they have worked for a statement of their character and professional skill. Letters addressed to senior medical officers, care of this

Directorate General will be forwarded. A released medical officer may obtain a certificate of service based on the whole of his service by applying to the Under Secretary of State, Air Ministry (A.P.9), Kingsway, London, W.C.2.

Vasectomy and Sterilization

Lieut Col F R W K ALLEN IMS (Berar India) writes. With reference to the medico legal case reported in the *Journal* of Jan 18 (p. 118) under the heading 'A Sterilized Husband' I should like to point out that a vasectomy is not 100% guarantee of a man being unable to impregnate a woman. I know of a case where vasectomy was performed and after a lapse of a year spermatozoa were found in the seminal fluid. I was present at the operation and I have seen the recent seminal fluid under the microscope.

Books for Germany

Dr E M VERMEHREN writes. The Agency for Intellectual Relief in Germany, recently founded under the patronage of Cardinal Griffin, the Bishop of Chichester, and the Master of Balliol is trying to help responsible Germans to reconnect themselves intellectually with the life and thought of Western civilization. It plans to establish in the British Zone several English lending libraries where important English publications of recent years will be available to qualified German readers who will themselves both run the libraries and select further titles. Specialized literature will be sent to institutions and individuals in Germany who need them for important work. Lists sent to us by German universities name the following medical books as urgently wanted: Joslin E P et al *The Treatment of Diabetes Mellitus* 7th edition Kimpton, 35s. 1941. Brock, Samuel *The Basis of Clinical Neurology* 2nd edition Williams and Wilkins \$5.50 1945. Wright, Samson *Applied Physiology* 7th edition Oxford University Press 25s. 1940. Wiggers C J *Physiology in Health and Disease* 4th edition Lea and Febiger \$10.00 1944. Boyd W *Pathology of Internal Diseases* 4th edition Lea and Febiger \$10.00 1944. Burrows, H *Biological Action of Sex Hormones* Cambridge University Press 42s. 1945. Darling H C *Rutherford Surgical Nursing and After treatment* 9th edition Churchill 12s. 6d. 1946. Todd, J C, and Sanford, A H *Clinical Diagnosis by Laboratory Methods* 10th edition Saunders 36s. 1943. Could we Sir, through the courtesy of your columns appeal to your readers for help, not only to get these special books but also for our work in general? We need both money—£5,000 in the next six months—and books but only those books for which a demand has been expressed by the German readers 'who have been spoon-fed much too long already and should at last be invited freely to select their intellectual diet.' Those of your readers who have books to spare which they think suitable are invited to send a list to our treasurer. They will then be informed which of the books are wanted, and where they should be sent. Contributions in money should be sent to the Hon. Treasurer, C P Kinnmonth, 4, Chapel Row, Wheeler End, High Wycombe, Bucks. We are trying to fight that intellectual starvation which in the words of our patrons, "remains, after famine, the gravest immediate danger facing us in Germany, and it threatens, if allowed to persist, to destroy all chances for the reintegration of the German people into a peaceful and prosperous Europe." Surely Sir such a cause cannot fail to engage both the sympathy and the generosity of the majority of your readers?

Correction

In the *Supplement* of March 22 (p. 38) under the heading "Salaries of Medical Practitioners Engaged by Local Authorities on a Sessional or Case Basis," the fee paid general practitioners for diphtheria immunization when visiting a child at home at giving injections there is 6s, not 6s 6d as stated.

In the letter from Dr J P McGowan (March 22, p. 389) the word "internationally" in the second sentence of the third paragraph should be 'intra nationally'.

A STUDY OF THE SURGICAL ANATOMY OF THE VAGINA, WITH SPECIAL REFERENCE TO VAGINAL OPERATIONS

BY

WILFRED SHAW, MD Cantab, FRCS, FRCOG

Surgeon in charge of the Obstetrical and Gynaecological Department St Bartholomew's Hospital London
Gynaecologist St Andrew's Hospital Dollis Hill

The Vulva and Anterior Vaginal Wall

The fold of skin containing the body of the clitoris is usually well defined. On each side is a groove, lateral to which lies the inner fold of the labium majus. The prepuce of the clitoris forms a hood over the glans, and on each side passes downwards into the labium minus. The labia minora are also attached to the under surface of the glans at a point in the midline which corresponds to the frenulum. These anatomical relations are not always carefully illustrated in gynaecological diagrams. On each side of the urethral meatus is a small depression which is perhaps best referred to as the *parameatal recess* (Fig 1). The recess is well defined in virgins and is best displayed by pulling the labia minora outwards at the level of the meatus. The recess is never well marked in severe cases of prolapse, and it is usually not well defined in women of post-menopausal age. In front, the remains of the hymen terminate in the midline at a point about $1/6$ in (0.4 cm) below the external meatus, but the termination is variable, and in a multipara the hymen sometimes passes into the posterior lip of the external meatus.

If a nullipara is examined in the lithotomy position with a Sims speculum introduced to retract back the posterior vaginal wall, the anterior vaginal wall can be seen to be held up and supported by the underlying tissues. It is therefore wrong to maintain that the anterior vaginal wall is supported solely by the perineum and the levator ani muscles.

In front, below the hymen in the anterior vaginal wall, about $1/4$ in (0.6 cm) below the urethral meatus, is a transverse groove. This groove is best displayed if the cervix is pulled down with a vulsellum forceps, and it is often well defined in prolapse of the anterior vaginal wall. It is believed that the groove indicates the posterior margin of the urogenital diaphragm. It is suggested that this groove should be named, and a convenient terminology might perhaps be the *submeatal sulcus*.

About $1\frac{1}{2}$ in (3.8 cm) from the meatus in the anterior vaginal wall is a second groove which is nearly always well defined. The groove represents the approximate position of the junction of the urethra with the bladder, and the distance between the two grooves is usually about $1\frac{1}{4}$ in (3.2 cm). The groove has a slight convexity in the direction of the meatus, and it is suggested that it should be called the *transverse sulcus of the anterior vaginal wall*. The distance between the submeatal sulcus and the transverse sulcus is about $1\frac{1}{4}$ in. It will be shown that the transverse sulcus is

formed as the result of the fusion of the underlying fascial tissues and represents the upper limit of a ligament which will be described later. Between the two sulci the rugae of the anterior vaginal wall are arranged more or less transversely, but the vaginal wall is attached loosely to the underlying tissues so that rugose pouches are formed. Unless the tissues have been damaged in childbirth, or unless the patient is of menopausal or post-menopausal age, a specialized fold of skin can be distinguished which passes from the lateral vaginal wall deep to the hymen to the vicinity of the submeatal sulcus. This fold is small and is best referred to as the *oblique vaginal fold*. Its significance is unknown, but below and lateral to it is a recess, lying lateral to the urethra, which is best referred to as the *para-urethral recess*.

If the anterior vaginal wall is followed down towards the cervix the limit of the bladder is indicated by a convex groove directed towards the cervix. In cystocele the bladder prolapses between the transverse vaginal sulcus and this *bladder sulcus* (Fig 1), and it is obvious that very little supporting tissue intervenes between the bladder and the vaginal wall—far less than is found between the submeatal sulcus and the transverse vaginal sulcus in the vicinity of the urethra. Between the transverse vaginal sulcus and the bladder sulcus the rugae are arranged according to a definite pattern. Immediately below the transverse sulcus their direction is transverse, but subsequently they become arched, with the convexity of the arch directed towards the urethral meatus. Further upwards towards the cervix they become transverse, and, finally, slightly convex near the bladder sulcus. The arching of the rugae is caused by the adhesion of the vaginal wall in this neighbourhood to the underlying fascial tissues.

Definition of the Fascial Layers

The fascial layers which lie deep to the anterior vaginal wall can be demonstrated at operation and by cadaver dissection in cases of cystocele in the following way. The cervix is pulled down with vulsellum forceps and firm traction applied both downwards and posteriorly so that the anterior vaginal wall is stretched. An incision is made in the midline, starting at about the level of the transverse vaginal sulcus and extending below the bladder sulcus to reach the front of the cervix. On each side, from the lower end of this midline incision, an oblique or a transverse incision is made (Fig 2). In the operation of anterior colporrhaphy the direction of the lateral incision depends

upon the severity of the cystocele and upon the amount of the anterior vaginal wall which is to be removed. Kocher's forceps are now applied to the lower angles of the vaginal flaps and downward traction exerted. With experience it is possible to reach the correct layer of cleavage with the first incision, but if there is any doubt about the correct layer, gentle traction, applied downwards and laterally to the Kocher's forceps, will gently tear through the tissues until the vesico-vaginal space is opened up. Firmly attached to the vagina is a well-defined layer of fascia called the vaginal fascia, while covering the bladder is a much thinner layer of tissue which forms the vesical fascia. The vesico-vaginal space lies between these two

the vaginal wall to move upon the underlying fascial layers. It is for this reason that the rugose vaginal pouches are found in this area.

Discussion

Operations for prolapse are performed so often that most of the above points are well known. In the average case of prolapse of the anterior vaginal wall the submeatal sulcus and the transverse vaginal sulcus are well defined. Though the two sulci are obvious, little attention has been paid to them previously, and it is one of the purposes of this paper to draw attention to their significance. Exceptions, however, are not uncommon. Sometimes other sulci can be seen between the submeatal sulcus and the transverse vaginal sulcus, and are caused by the arrangement of the pouches of the vaginal wall in this neighbour-

FIG 2—The incisions for anterior colporrhaphy. The oblique lines indicate the direction of the incisions for different degrees of prolapse of the anterior vaginal wall.

FIG 3—The appearance after the dissection of the vaginal flaps. (1) Post urethral ligament. The well defined cranial border is emphasized. In the illustration the vesico vaginal space has been opened up, and the vaginal fascia (2) remains attached to the vaginal wall. (3) Bladder septum. (4) Vesico cervical ligament.

fascial layers. The dissection is now carried in an upward direction as far as the level of the transverse vaginal sulcus. The vesico-vaginal space is always easy to define except in advanced cases of cystocele when the bladder wall has been prolapsed for a long time. In old-standing cases of this kind the vesical and vaginal fascias fuse, so that thick strands of tissue pass between the two fascial layers, and these must be cut through with a scalpel to allow the dissection to proceed in the correct layer of cleavage. Except in these old-standing cases, if once the vesico-vaginal space is opened up, the vesical and vaginal fascias can be separated from each other with the help of gauze wrapped round the finger. Moreover, the separation is bloodless, for there is no communication between the vascular systems of the two fascial layers. Anteriorly, at the level of the transverse vaginal sulcus, the vaginal fascia fuses with the vesical fascia so that there is no true vesico-vaginal space between the transverse vaginal sulcus and the submeatal sulcus. It is therefore necessary to use a scalpel to separate the vagina from the fused fascial layers. The connecting tissues are, however, loose, and they allow

hood. Sometimes, in severe degrees of prolapse, the transverse vaginal sulcus is held up almost in its normal position. It is of interest that such patients rarely complain of imperfect control of micturition.

The nomenclature of the vaginal and vesical fascias is not universally accepted even at the present day. Even in recent descriptions of vaginal operations the subvaginal fascial layers are referred to as the pubo-vesical fascia, pubo-vesical ligament, paravaginal fascia, and pubo-cervical ligament, and some authors even describe the fascial layers as forming part of the urogenital diaphragm. Usually the vaginal fascia is referred to under these terms, for the vesical fascia is never so well defined, presumably because the bladder alters so much in size.

Much has been written of the fascial tissues of the pelvis particularly by the Viennese—Tandler (1926), Halban and Tandler (1907), and Peham and Amreich (1934)—but very important contributions have been made both in this country and in America. The term "pelvic fascia" should be restricted to the dense fascial tissues covering the levator ani and obturator internus muscles. All other fascial layers

should be considered as forming the endopelvic fascia. This distinction is of the greatest importance, because the endopelvic fascia always contains plain muscle cells and has an intimate relation to the adventitia of the pelvic veins, with the result that the small veins of the pelvis form plexuses in cavernous-like tissue. One of the functions of the endopelvic fascia is to fix and support the pelvic organs. At the same time the endopelvic fascia is arranged in such a way that it allows for distension of the pelvic organs. Lastly, it regulates the venous return at different degrees of distension.

Pcham and Amreich showed that the basal portion, or ground bundle of the endopelvic fascia, lies on the upper surface of the levator ani muscles on each side of the midline and passes backwards to terminate in Mackenrodt's ligament. Passing upwards from the ground bundle

great difficulty if Fothergill's technique is followed. It is for this reason that I always start vaginal operations on the anterior vaginal wall not immediately below the urethra but from a point near the cervix.

The Post-urethral Ligament

The vaginal and vesical fascias fuse in the vicinity of the transverse vaginal sulcus, and pass downwards to become attached to the margin of the urogenital diaphragm at the submeatal sulcus. In addition, the fused fascial layers form a strong supporting layer of white tissue, and its function is clearly to support the urethra. The fused fascial layers should therefore be regarded as forming a ligament; and I suggest that the name *post-urethral ligament* (Fig 3)

FIG 4

FIG 5

FIG 6

FIG 5—The method of introducing the sutures after excising all redundant vaginal flaps. In front the stitch is intended to suture the vaginal wall to the post-urethral ligament, and at the same time to suture the post-urethral ligament to the front of the uterus. The lower sutures pass through the vaginal wall and the vaginal fascia and then through the front of the cervix.

FIG 6—Technique for the operation of vaginal hysterectomy for prolapse before suturing the pedicles together. (1) Post-urethral ligament (2) Bladder (3) Peritoneum (diagrammatic) (4) The pedicle containing the round ligament, the ovarian ligament, and the Fallopian tube (5) The pedicle containing the uterine vessels (6) The pedicle containing the utero sacral ligament. (a) The suture is passed through the vaginal wall then through the peritoneum covering the bladder, the procedure being repeated on the opposite side. (b) The suture is passed through the vaginal wall, the vaginal fascia, the first pedicle, and then through the post-urethral ligament, the procedure being repeated on the opposite side. (c) The suture is passed through the vaginal wall and the utero sacral pedicle, and repeated on the opposite side.

are septa which fix the bladder, vagina, uterus, and rectum, and it is in these septa that the blood vessels pass to reach the pelvic organs. If dissections are made between the fascial layers an almost bloodless operation can be obtained, which has been emphasized by Spalding (1926) particularly, for the vascular systems of the different fascial layers and septa do not communicate except at well-defined points.

The fascial layers are difficult to distinguish by histological examination, as Goff (1931) has emphasized, but they can be defined at operation. For example, the vaginal fascia is utilized in many operations for cystocele, as in Halban's operation, and many American surgeons employ a rather similar technique. Fothergill (1917) as much as anyone realized the importance of the endopelvic fascia, and in the operation known by his name the vaginal fascia and the vaginal wall are sutured to the front of the cervix. Nevertheless, the vesico-vaginal space is exposed only with

should be applied to this band of tissue. The upper cranial margin of the post-urethral ligament is usually well defined, and it is this margin which is responsible for the formation of the transverse vaginal sulcus. In the midline, the post-urethral ligament is adherent to the bladder for a short distance upwards towards the cervix, and it is for this reason that the rugae of the anterior vaginal wall are arched in this area, for here the anterior vaginal wall and its vaginal fascia are fused to the vesical fascia. On each side the ligament is attached to the pubic ramus as far down as the junction of the ramus of the pubis and of the ischium. It is important to bear in mind that the sheet of tissue which forms the post-urethral ligament has an inclination which corresponds to that of the axis of the vagina. It must therefore be almost perpendicular to the urogenital diaphragm. There is no reason to believe that it forms part of the urogenital diaphragm in any way at all. Clearly, it has a corresponding position, and perhaps

serves a somewhat similar function to Denonvillier's fascia (Tobin and Benjamin, 1945) or the recto-prostatic fascia. The terminology I have suggested is tentative, but it seems to me preferable to the other alternative—namely, pubo-urethral. It is one of the main purposes of this paper to draw attention to the post-urethral ligament. I have studied the literature carefully, and I am convinced that the importance of this ligament has not been emphasized. Some writers seem to confuse the ligament with the membranous sphincter. I suppose that most gynaecologists regard the ligament as being part of what they term the pubo cervical fascia or pubo-vesical fascia. If careful dissection is made, the well-defined cranial limit of the ligament, combined with its dense consistency, impresses me with the importance of regarding the ligament as a separate entity. I differ from Amreich in the interpretation of the ligament, for he regards this as partially surrounding the urethra, whereas I interpret it as a transverse sheet of tissue lying below and behind the urethra. The attachment of the ligament to the pubic ramus is of very great importance, and obviously the ligament must support the urethra. Furthermore, in cases of urethrocele the ligament is stretched and relaxed. The relation of the upper limit of the post-urethral ligament to the junction of the urethra and the neck of the bladder seems to be variable. Efforts have been made to define the upper limit with the help of a cystoscope during the operation of anterior colporrhaphy. It is well known that if a curved sound is passed into the female urethra a fold can be felt, as Jeff Miller (1932) has emphasized, at the point where the urethra joins with the bladder. The fold is produced by the inward pressure of the upper margin of the post-urethral ligament on the neck of the bladder.

The Vesico-cervical Ligament

This ligament is a continuation of the vesical fascia on to the anterior surface of the supravaginal portion of the cervix. It consists of a thin sheet of tissue which contains plain muscle cells and which has a linear attachment to the cervix. It is easy to define, and it is divided in both Fothergill's and Halban's operations. On each side of the vesico-cervical ligament lies the bladder septum, which is much thicker and more vascular, and which passes from the vesical fascia to the fascia covering the cervix. In the operation of anterior colporrhaphy a few fibres of the bladder septum must be divided before the bladder can be separated from the front of the uterus. Afterwards the separation is simple, and it can best be carried out with the help of a piece of gauze wrapped round the index finger.

The Vesico-cervical Space

This space lies above the vesico-cervical ligament and intervenes between the bladder and the cervix. It is bloodless and can always be accurately defined. It is bounded cranially by the vesico-uterine ligament, which is a reflection of the vesical fascia from the top of the bladder on to the front of the uterus in the neighbourhood of the junction of the body with the cervix. The ligament is never well defined, but it is seen best at abdominal hysterectomy, when it must be cut through before the bladder can be separated from the front of the uterus.

Technique of Anterior Colporrhaphy

The method which I employ at the present time is based upon the identification of the different ligaments and fascial layers. The view is taken that the direct support of the bladder, between the transverse vaginal sulcus and the bladder sulcus, consists only of the vesical and vaginal fascias together with the anterior vaginal wall. The indirect supports are not being considered here, for they must be dealt with by more elaborate procedures. If the fascial

layers have been stretched, and particularly if the patient is asthenic with loss of plain muscle tone of the fascial layers, a cystocele will develop. Fundamentally, the operation consists in mobilizing the bladder, retracting it upwards and anteriorly, and then deliberately suturing the cranial margin of the post-urethral ligament to the front of the uterus in the neighbourhood of the utero vesical pouch of the peritoneum. In this way the space through which the bladder can herniate is obliterated.

A vertical incision is made in the anterior vaginal wall, with lateral incisions at the lower end, as already described. The vesico-vaginal space is opened up and the lateral flaps are separated from the vesical fascia with the help of gauze wrapped round the finger. Beyond the level of the transverse vaginal sulcus a scalpel must be used to cut through the fascial tissues to separate the vaginal flaps from the post-urethral ligament, for here there is no clearly defined space between the vaginal walls and the post-urethral ligament. If the dissection proceeds too far laterally at this level, cavernous sinuses are opened up, and this should be avoided.

The next step is to cut through the vesico cervical ligament and a few fibres of the bladder septum, and then to strip and separate the bladder from the cervix in the vesico cervical space until the bladder can be pushed back as far as the margin of the post-urethral ligament (Fig 4). The redundant vaginal tissues of the flaps, including the vaginal fascia, are then excised. If the separation has been good only a small number of blood vessels require ligation—namely those belonging to the cut edges of the vaginal walls and perhaps a few small vessels in the bladder septa. If necessary, the vaginal fascia can be separated from the flaps and used to form a reduplicating layer, but this is regarded as unnecessary in the average case. If the cystocele is extensive the bladder may be invaginated either by means of a purse-string suture or by a series of reefing sutures.

The post-urethral ligament is sutured to the front of the uterus as follows (Fig 5). A suture of No 2 chromicized catgut is passed through the cut edge of the vagina about $1\frac{1}{2}$ in (3.8 cm) below the urethra, starting on the patient's left side. The suture is now passed through the post-urethral ligament and then through the front of the cervix near the utero-vesical pouch. It is then passed through the post-urethral ligament on the other side of the midline and, finally, through the vaginal wall of this side at a point $1\frac{1}{2}$ in below the urinary meatus. The assistant now pushes back the bladder, and when the suture is tied the post-urethral ligament becomes sutured directly to the uterus. As a result, the space through which the bladder can prolapse is obliterated completely and a firm ligamentary support by means of the post-urethral ligament is given to the bladder. Various modifications are possible. Sometimes the post-urethral ligament can be sutured direct to the front of the uterus by a series of interrupted sutures arranged to form a horizontal layer. In severe cases of cystocele more than one of these key sutures can be introduced. I believe that the only technique comparable to the above is that described by Lockyer (1913).

The next part of the operation consists in suturing the cut edges of the vagina, including the vaginal fascia, to the front of the supravaginal portion of the cervix, just as in the original Fothergill technique. The cut anterior vaginal wall between the cranial margin of the post-urethral ligament and the meatus is now dealt with. The pouches are redundant and a fair amount of vaginal tissue can be excised. If there has been stress incontinence a shelf can be fashioned by a series of interrupted Lembert sutures introduced through the post-urethral ligament. The operation

is of fundamental importance in the treatment of stress incontinence associated with cystocele, and the end-results are excellent, for the urethra is stretched and elongated both upwards and backwards as the result of the operation.

Modification of Fothergill's Operation

A midline incision is made in the anterior vaginal wall and the lateral incisions are placed transversely. The vaginal flaps are dissected free as in an anterior colporrhaphy, and the bladder is mobilized in the same way. I suture the post-urethral ligament to the front of the upper part of the supravaginal portion of the cervix, as in the technique for anterior colporrhaphy. The lateral incisions are continued round the back of the cervix and the cervix is then amputated. If the prolapse of the uterus is of a severe degree not only the bladder septum but the basal portions of Mackenrodt's ligament are sutured to the front of the cervix. The object is to take up the slack in a lax ligament, and the procedure is usually successful. Moreover, the suture tends to make the uterus ante-flexed. Subsequently, the raw surface of the cervix is covered by the Bonney-Sturmdorf technique. Gough's (1931) method is a great help if there is extensive prolapse of the upper part of the posterior vaginal wall.

Vaginal Hysterectomy for Prolapse

This operation is perhaps the most suitable form of operative treatment for post-menopausal women with severe degrees of prolapse of the uterus. The operation is relatively simple provided that the cervix can be pulled down outside the vaginal orifice, and provided that the uterus is not much enlarged. The method is used if patients are in the child-bearing period of life and suffer from symptoms, such as menorrhagia, which demand surgical or radiological treatment, and have a moderately severe degree of prolapse of the uterus. The technique becomes difficult if the uterus does not prolapse to the extent that the cervix can be pulled through the vaginal orifice. My impression is that most patients with prolapse maintain that they feel very much better in themselves if the uterus is removed, which is a factor of very considerable importance.

Technique

A midline incision is made in the anterior vaginal wall from which pass transverse incisions near the cervix. The technique of an anterior colporrhaphy is employed to mobilize the bladder after cutting through the vesico-cervical ligament. The vesico-cervical space is identified, the bladder retracted upwards, and the peritoneum of the utero-vesical pouch exposed. This procedure is very simple provided that the vesico-cervical space has been opened up cleanly. The peritoneum is now cut through and the body of the uterus pulled down through the opening in the utero-vesical pouch. The fundus of the uterus can usually be hooked down with a finger. In difficult cases vulsellum forceps or uterine holding forceps are necessary. The uterus is now removed by the method advocated by Franz and by Mayo. Curved clamps with horizontal striations are applied on each side of the uterus to contain the ovarian ligament, the Fallopian tube, and the round ligament. The tissues are cut through on the uterine side of the clamps. A second pair of clamps is now applied to the uterine arteries at the base of the broad ligaments and the uterus further separated with a scalpel. At this stage of the operation the uterus is drawn downwards which exposes any prolapse of the peritoneum of the pouch of Douglas. This is regarded as being an important step in the operation and it is quite simple to separate cleanly any prolapsed peritoneum of Douglas's pouch and to divide it along its attachment to the sigmoid. The next step in the operation is to hold up the cervix with vulsellum forceps and to finish the circular incision through the vaginal wall at the back of the cervix. Clamps are placed on each side to include the utero-sacral ligaments. After this the uterus

is removed completely by cutting through the intervening tissues with a scalpel. In simple cases only six clamps are required. More are necessary if the uterus is enlarged or if there is difficulty in pulling down the uterus. In vaginal hysterectomy for prolapse I never now employ the method of dividing first the lateral supports to pull down the uterus. In my hands it is much more difficult, and I place great emphasis on mobilizing the bladder and then pulling down the fundus of the uterus to ensure that the ureters are well away from the operation area. Nor do I first open Douglas's pouch, because I maintain that it is of the greatest importance to remove as much peritoneum as possible from the region of Douglas's pouch and this can best be done through traction on the uterus to expose the redundant peritoneum.

A shelf is now formed to support the bladder (Fig. 6). A suture is passed through the cut vaginal wall as in the anterior colporrhaphy operation, $1\frac{1}{2}$ in (3.8 cm) below the urinary meatus. It then passes through the post-urethral ligament, then through the peritoneum at its cut edge near its attachment to the bladder. The suture then passes through the other side of the post-urethral ligament and finally through the vaginal wall. The object of the stitch is to join the peritoneum to the post-urethral ligament and to obliterate the space through which the bladder prolapses. If the cystocele has been of a moderate or slight degree this stitch alone helps greatly to hold back the bladder, but if there has been a severe degree of cystocele the bladder must first be invaginated with a purse-string suture. The next stitch passes, as before, through the vaginal wall, then through the post-urethral ligament, and then through the tissues enclosed in the first clamp—namely, the ovarian ligament, Fallopian tube, and round ligament. The suture is then passed through the tissues contained in the corresponding clamp of the opposite side, then through the post-urethral ligament, and finally through the vaginal wall. Neither suture is tied at this stage of the operation. The next step is to ligature together the tissues of the two sides as in Mayo's operation. The untied sutures are now tied. The first suture draws the post-urethral ligament upwards under the trigone of the bladder to support the bladder as in the operation of anterior colporrhaphy. The second suture, after being tied, draws together the shelf formed by the round ligaments, the ovarian ligaments, and, to a minor extent, the Fallopian tubes, and the shelf is anchored to the post-urethral ligament. Lastly, the cut edges of the vaginal wall are sutured together with a series of interrupted stitches.

One of the most difficult technical problems in the operation of vaginal hysterectomy for prolapse is to prevent the subsequent development of a hernia of Douglas's pouch. If the prolapse is of a severe degree, I always begin the operation of colpoperineorrhaphy before closing completely the posterior part of the incision. If the patient is elderly and has agreed that the vagina can be made so small that further sexual intercourse will be impossible, the problem is simple, for the utero-sacral ligaments, the rectal septa, and even the two levator ani muscles can be sutured to the posterior part of the shelf. The vagina can then be narrowed and shortened and an excellent prognosis can be given. If, however, the patient wishes to continue her sexual life the problem is much more difficult. For its solution the vagina must not be shortened or narrowed to the extent of preventing sexual intercourse, yet care must be taken to avoid the recurrence of prolapse. It may be most convenient if the method I use for colpoperineorrhaphy is now described.

Colpoperineorrhaphy

Lane's tissue forceps are attached to the vaginal wall in the midline well above the level of the levator ani muscles. Two further Lane's forceps are applied on each side to the termination of the labium minus into the remains of the fourchette. A midline incision is made through the vaginal wall to meet a second transverse incision made with a scalpel along the line of the remains of the fourchette. In

this way the two flaps are demarcated, and the vaginal tissue they contain is dissected clear of the underlying tissues, which consist mainly of scar tissue in prolapse cases. The technique is different from that of the operation of anterior colporrhaphy, for the dissection is made with a scalpel between the vaginal wall and the vaginal fascia. Great stress is placed upon dissection of the vaginal wall laterally on each side along the course of the remains of the hymen, otherwise the levator ani muscles will not be sufficiently exposed. The vaginal fascia is now cut through as in Amreich's technique (Peham and Amreich, 1934), high up above the level of the levator muscles, so that the recto-vaginal space is exposed. If the rectum is now retracted back with a finger the rectal septa, with their veins and arteries, can be exposed. The septa represent the downward continuation of the utero-sacral ligaments. They terminate in the ground bundle on the upper surface of the levator muscles. Their veins and arteries are easily torn, and they require careful ligation. The next step is to excise the redundant vaginal tissue contained in the flaps.

With cases of complete procidentia and after vaginal hysterectomy for prolapse the incision is continued upwards until it joins the incision at the top of the vagina. Redundant vaginal tissue is excised when necessary. Bleeding comes from the descending branches of the vaginal artery, which must be ligatured in the space between the vaginal fascia and the vaginal wall. In cases of prolapse of Douglas's pouch it will be necessary to excise the peritoneal sac if a vaginal hysterectomy has not been performed. A recurrence of a hernia of Douglas's pouch can be prevented by suturing the two utero-sacral ligaments and the upper parts of the rectal septa direct to the shelf of tissue which has been formed in the operation of vaginal hysterectomy. In severe cases the upper and anterior parts of the two levator muscles must be identified and then sutured to the shelf as in Everard Williams's technique, but this procedure almost always shortens and narrows the vagina. The vagina may therefore be shortened in two ways—either by excising a great deal of redundant vaginal tissue in its upper part or by suturing the levator ani muscles to the shelf formed from the two broad ligaments. Recurrence of a hernia of Douglas's pouch can be prevented with certainty if the vagina is shortened drastically. If, however, the patient is to resume sexual relations the vagina must be left long, and in these cases only the utero-sacral ligaments are sutured together.

The next step is to suture together the two levator ani muscles. Great stress is placed upon suturing them together at least 2 in (5 cm) above the level of the vaginal orifice, and for this to be done the muscles must be exposed as far forwards as this. Two fingers placed in the aperture thus formed will indicate how narrow and how long the vagina has been made. The first sutures through the two levator muscles should include the rectal septa, and this again is regarded as an important step in the operation. The two levator muscles are now sutured together with interrupted stitches, and the vagina fashioned into the shape of a hollow tube in the usual way.

Operations for Stress Incontinence

These cases can be grouped into those in which the condition is associated with cystocele and prolapse of the uterus, and those in which only the urethra prolapses in the lower half of the anterior vaginal wall. In the prolapse operations, whether anterior colporrhaphy, Fothergill's operation, or vaginal hysterectomy for prolapse, the post-urethral ligament is sutured in such a way that it is stretched in a sagittal direction. Not only that, it is pulled upwards as well. Experience shows that many patients

have so much control that they find it difficult to pass urine until they are up and about. If the urethrocele is well marked, a series of reinforcing or reefing sutures are introduced through the post-urethral ligament on each side of the urethra to form, when tied, a further support to the urethra. In my view, it is fundamentally wrong to mobilize the urethra from the pubic ramus by cutting through the post-urethral ligament as recommended by some gynaecological surgeons. The end-results for stress incontinence in these cases are extremely satisfactory.

The difficult cases are when stress incontinence is complained of without prolapse of the bladder. In these cases an effort is always made to separate the bladder from the vaginal wall and to stitch the upper edge of the post-urethral ligament to the front of the cervix. If this can be done the end-results are good. Alternatively, the following technique is employed. A midline incision is made through the lower parts of the anterior vaginal wall and two vaginal flaps are dissected away superficial to the post-urethral ligament. The incision is continued upwards towards the cervix and the bladder separated from the anterior vaginal wall by working upwards towards the situation of the cervix. The post-urethral ligament is now separated from the vaginal wall laterally. The next step is to pass a series of mattress sutures. These start cranially, first through the vaginal wall on one side of the upper limit of the incision then through the post-urethral ligament, and finally are brought down through the vaginal wall at a corresponding point at the other side of the incision. When this suture is tied the post-urethral ligament is drawn upwards and fixed to the anterior vaginal wall much higher up than normally. Two or three sutures of this kind should be inserted. Subsequently the post-urethral ligament is reinforced by a series of Lembert's sutures, which form an additional shelf below the urethra. The end-results of this operation are extremely good. The Stoeckel-Goebel, and the more modern Aldridge (1942), method should perhaps be used only when this relatively simple operation has failed.

Summary

A description has been given of the different folds and sulci in the anterior vaginal wall, and an explanation has been offered of their arrangement.

Attention has been directed to the condensed fascial layer which intervenes between the urethra and the anterior vaginal wall. The topography of this layer of tissue has been described, and it is suggested that the layer should be called the post-urethral ligament.

The methods of defining the different fascial layers and the intervening spaces that surround the vagina have been described.

A description has been given of the various methods of surgical technique in the treatment of prolapse which make use of the post-urethral ligament.

TREATMENT OF REITER'S SYNDROME BY GOLD SALTS

BY

R. R. WILLCOX, MB, BS

G. M. FINDLAY, CBE, MD, DSc, MRCP

AND

A. HENDERSON-BEGG,* MB, ChB

Arthritis and a non-specific urethritis, sometimes associated with conjunctivitis, have been described in relation to a number of different conditions. One of us (Findlay, 1946) has pointed out that in experimental animals—rats and mice—certain strains of pleuropneumonia-like organisms give rise to arthritis and conjunctivitis, while the same lesions have been noted in bovine pleuropneumonia and in contagious agalactia of sheep. In addition, pleuropneumonia-like organisms have been isolated from the urethra of normal persons and more frequently from those of patients with non-specific urethritis. In view of these findings it seemed to be worth while to attempt to isolate pleuropneumonia-like organisms from the conjunctiva and joint fluids of patients suffering from what has, perhaps prematurely, been called Reiter's disease.

Attempts to Isolate Pleuropneumonia-like Organisms

Two patients with arthritis and urethritis, one of them also having conjunctivitis, have been investigated for the presence of pleuropneumonia-like organisms by culture of the joint fluid and blood on suitable media rich in animal protein and by inoculation of blood and joint fluid into mice. The culture of pleuropneumonia-like organisms from the urethral tract is of questionable significance at this stage in view of reports by some workers of successful culture from the normal genital tract. In neither of these cases were positive cultures obtained from the blood or joint fluid. Blood and joint fluid, 0.2 ml, from both cases was injected into the dorsum of the hind feet of 12 mice. One of these mice developed arthritis of the joint after an incubation period of 15 days. We failed to transmit the condition to other mice.

No definite conclusions can be drawn from the production of arthritis in a single mouse. Mice are naturally infected with a number of strains of pleuropneumonia-like organisms some of which may cause arthritis, in addition it must be remembered that certain rodent strains of pleuropneumonia-like organisms are species-specific. At present the majority of strains of pleuropneumonia-like organisms isolated from man have not been shown to be capable of producing arthritis in rodents, it is therefore merely an assumption that the hypothetical organisms from cases exhibiting Reiter's syndrome should be arthritis-producing in rats or mice.

One peculiarity shown by pleuropneumonia-like organisms is their sensitivity to gold salts. Thus it seemed worth while to study the reaction of patients with Reiter's syndrome to the injection of gold salts. Since these cases were treated Baxter (1946) has reported a case in which there was a slow response to 'myocrisin'. Details of the treatment of two cases are briefly as follows.

Case 1

A man aged 22 was admitted to hospital on July 17, 1946. In June he had been treated in Germany for non-specific urethritis with 70 g. of sulphathiazole given over five days. There was no further previous history of eye trouble.

*Wellcome Tropical Research Laboratories London

gonorrhoea, or other venereal disease. The patient was admitted on account of a recurrence of the urethritis. He also had a dry balanitis of one week's duration, with numerous pin-point ulcers on the glans penis. A urethral smear showed many pus cells, but gonococci were not present, the urine was hazy. Three dark-ground tests were performed on exudate obtained from the balanitis with negative results for treponemata. The blood Wassermann and Kahn reactions were both negative. He was given 24 g. of sulphathiazole over four days, and on July 20 he complained of swelling of the terminal joint of the left ring-finger. Within two days the middle joint of the right middle finger and the right hallux were also red, swollen, and tender. A purulent urethral discharge was still present and the urine was slightly hazy. A gonococcal complement-fixation test on July 22 was negative, the blood sedimentation rate was 85 mm in one hour.

On July 24 an intravenous T.A.B. vaccine, 50 000 000 organisms, was given with good response, the maximum temperature reaching 103° F (39.4° C). The following day there was improvement in the joints but by the 29th they had relapsed somewhat. He was then given 2 400 000 units of penicillin (40 000 units three-hourly for seven and a half days), and by Aug 5 the arthritis of the toe had improved, but improvement in the fingers was only slight. The urethral discharge was still detectable in the early morning, when many pus cells were present, the urine was clear. On Aug 8 a blood count showed 10 600 white cells per cmm (66% polymorphs, 30% lymphocytes, 3.5% mononuclears, 0.5% eosinophils). On Aug 10 an effusion appeared in both knees, this disappeared spontaneously from the right side within four days. On Aug 18 the fingers were no longer red but still swollen, as was the right big toe. There was a marked effusion in the left knee and the balanitis had not cleared. The following investigations were done: blood sedimentation rate, 30 mm in one hour, haemoglobin, 12.7 g %, packed cell volume, 40%, white blood count, 12 000 (polymorphs 84%, lymphocytes, 14%, mononuclears, 2%), blood uric acid, 3.3 mg per 100 ml. Skiagrams of the affected joints showed no bony changes. Stool culture revealed no pathogens.

On Aug 18 conjunctival and urethral smears were taken for special examination and the left knee was aspirated. It was then decided to employ gold therapy. Myocrisin was given intramuscularly. The dates of the various injections and the relevant sedimentation rates are as follows.

Date	BSR	Myocrisin
Aug 18	30 mm in 1 hour	—
21	—	0.01 g
26	—	0.02 g
27	31	—
Sept 2	—	0.02 g
7	18	0.025 g
13	11	0.025 g
19	12	0.05 g
25	—	0.05 g
Total in 5 weeks		0.2 g

The temperature was taken four-hourly, the urine was tested daily for albumin, the skin closely watched for dermatitis, and a blood count done twice weekly. No untoward reactions were noticed. The balanitis rapidly cleared, though the urethral discharge resolved but slowly. The joints showed slow but steady improvement.

On Sept. 18 there was a brief setback, fluid reappeared in the left knee and there was a slight swelling of the left ankle. This subsided within two days and the patient was discharged to duty on Sept. 24. On Sept. 19 Flexner vaccine was instilled into the right eye (see below), with negative results.

Case 2

A man aged 23 was admitted to hospital on Aug. 20, 1946. In May 1944 he had had acute gonorrhoea, which was treated with sulphathiazole, 5 g daily for five days. In December 1944, he developed pain and swelling in the right foot associated with balanitis, and gonococcal arthritis was diagnosed. He was treated with a penicillin drip (dosage unknown) without effect, and later received T.A.B. and physiotherapy, by April, 1945,

he had fully recovered. Since that date he had been well except for occasional conjunctivitis and a very slight urethral discharge. There was no previous history of dysentery or venereal disease other than the above.

On Aug 13 he sought advice on account of a slight urethral discharge of one week's duration. A smear showed pus cells but no gonococci; he was given sulphathiazole 5 g daily for five days. On the following day he fell and injured his left knee. When he returned on Aug 20 he showed an improvement in the urethral discharge, but a marked effusion was present in the left knee; moreover, there was a severe bilateral conjunctivitis of two days' and a balanitis of six weeks' duration.

He was admitted to hospital and given 200 000 units of penicillin in five three-hourly doses of 40,000 units. On the 21st his urethral smear continued to show many pus cells, while the urine was hazy in two glasses. The blood Wassermann and Kahn tests and the gonococcal complement-fixation test were negative, blood count haemoglobin, 115%, red cells, 5,490,000, white cells, 10,600, polymorphs 61%, lymphocytes 35%, mononuclears 4%, urine albumin, sugar, ketones, bile negative, stool no pathogens found in culture, blood sedimentation rate, 6 mm in 1 hour. A skiagram of the knee revealed no bone injury.

On the following day urethral and conjunctival smears were taken for special examination and the left knee was aspirated. Gold therapy with myocrisin was then begun. Temperature recordings, daily urine examination for albumin, and skin inspection and blood counts twice a week did not reveal any toxic reactions. The dates and amounts of the myocrisin, together with the relevant sedimentation rates, are as follows:

Date	BSR	Myocrisin
Aug 22	12 mm in 1 hour	0.01 g
" 28	—	0.02 g
Sept 2	—	0.02 g
" 7	3 mm in 1 hour	0.025 g
" 13	4	0.025 g
" 19	5	0.05 g
" 25	—	0.05 g
	Total in 5 weeks	0.2 g

The eyes were treated locally with saline washes and resolution was rapid, both becoming normal within 72 hours. The balanitis showed steady improvement and had quite gone by Sept 2. The urine cleared within three days, but a morning urethral discharge persisted for three and a half weeks. The knee filled up again after the initial tapping, but had begun to subside when a second aspiration was performed on Sept 18 after which time it did not refill.

On the 19th Flexner vaccine was instilled into the right eye without result (see below). The patient was discharged to duty on Sept 25. There was no improvement with penicillin, though with gold therapy it was steady and maintained.

The Eye Test

The possible dysenteric origin of some cases of Reiter's syndrome has recently received considerable attention. Wood (1946) states that he succeeded in reproducing the sterile conjunctivitis in three cases by instilling a drop of Flexner vaccine into the eye. It was decided to apply this test to these cases. Flexner bacteria (mixed I-VI) were killed by heat at 55° C, and a suspension of 3,000 million organisms per ml was kindly prepared by Lieut-Col Archer, R A M C, to whom due acknowledgment is given. It produced no reaction in three rabbits or in two human controls.

A drop of this material was placed in the right eye in the above two cases and in a third case which had previously shown polyarthritides, urethritis, and conjunctivitis and had apparently recovered. No reaction was noted in any of these cases. None of these patients' sera showed any agglutination with strains of dysentery bacilli of the Shiga type. It may be of interest to note that cases of non-specific urethritis, arthritis, and conjunctivitis are not

uncommon in West Africans among whom Shiga dysentery is exceptionally rare.

Discussion

Although the hyperthermia is probably the most satisfactory treatment for patients with Reiter's syndrome, gold salts appear capable of producing a satisfactory cure. It is, however, unwise to assume from the therapeutic action of a particular drug in different diseases that the causative organisms of these diseases are necessarily related. Antimony salts, for instance, have a curative action in schistosomiasis and in infections due to *Leishmania* and trypanosomes. Penicillin is known to be valueless in diseases due to pleuropneumonia-like organisms, but streptomycin has been found to be curative in rodent arthritis due to similar organisms (Powell *et al*, 1946); its action in patients with Reiter's syndrome would be of interest. Further investigation of patients with Reiter's syndrome for the presence of pleuropneumonia-like organisms is desirable.

Conclusions

Apart from the production of arthritis in a single mouse by the injection of joint fluid from one patient, an investigation of two patients with Reiter's syndrome was negative for the presence of pleuropneumonia-like organisms.

Gold salts were curative in two patients with Reiter's syndrome not associated with bacillary dysentery, while penicillin and sulphonamides were of little value.

SCRUB TYPHUS VACCINE

ITS EFFECT ON SIXTEEN CASES INCUBATING THE DISEASE

BY

W. THOMSON WALKER, MBE, MA, MD

Late Major, R A M C Medical Specialist

On account of the high incidence of scrub typhus in Mandalay during the autumn of 1945 the D M S, Twelfth Army, decided that all troops in that area should receive scrub typhus prophylactic vaccine. Seven and a half litres of the special vaccine prepared in "Operation Tyburn" at the Wellcome Veterinary Research Station, Frant, Sussex (Buckland *et al*, 1945), was employed in 1-ml doses on three occasions at weekly intervals. All the inoculations were given during November, 1945, and, since this was the month of peak incidence of scrub typhus, local commanding officers were glad to co-operate in arranging inoculation parades.

Initially the intention was to inoculate half of each company so that the remainder would serve as controls in the evaluation of the efficacy of the vaccine, but the increasing incidence and the commanding officers' suspicion that it was something of an experiment resulted in a fresh instruction that all troops should be inoculated. Inoculation produced a slight local tingling lasting five minutes due to the formalin vehicle, but no immediate constitutional reaction resulted, though fever was reported in some cases; these are included among the 16 cases which form the basis of this report. In all 2,500 troops were inoculated with prophylactic vaccine.

It had been suggested that the bite of a mite could produce an eschar whether the trombiculid was infected with *ricettsiae* or not, so this mass-inoculation programme was made use of to carry out a routine skin examination in which search was made at the time of the first inoculation for eschar-like sores in all troops. It seems worth recording that, apart from cases which were subsequently shown to be incubating the disease, the presence of an eschar in an otherwise healthy man was not reported.

This paper is concerned solely with the immediate effect of the inoculation upon the course of the disease in 16 men who were inoculated fortuitously during their period of incubation of scrub typhus, the question of its prophylactic efficacy in respect of the remainder of the 2 500 inoculated had to be left to a successor.

Post-inoculation Cases of Scrub Typhus

All 16 cases had received one or more inoculations of the prophylactic vaccine between Nov 10 and 18, 1945, and were received into hospital between Nov 12 and 20. Eight had come from one unit and four from another unit in an adjacent site at Fort Dufferin, Mandalay. These 12 cases, arising apparently out of their inoculation a few days previously, not unnaturally gave rise to some alarm among the officers and other ranks (who totalled 450). Among the victims were the commanding officer and the second-in command of the unit most seriously affected. Careful examination of the cases showed that 14 of the 16 had typical eschars with lymphadenitis of related glands. This was most fortunate for me, for anxious and irate senior officers had to be faced with a very definite opinion as to whether any blame might attach to the inoculations which all area troops were in process of receiving. A reasoned explanation was accepted and the inoculation scheme proceeded with. All the cases were subsequently proved by Weil-Felix agglutination tests.

Of the 16 cases, 12 had received one inoculation of 1 ml of prophylactic vaccine before the development of symptoms, two had received two weekly injections of 1 ml, and two had, during and overlapping the incubation period, received three injections of 1 ml of the vaccine.

Classification into Four Groups

For descriptive purposes the cases have been divided arbitrarily into four groups, according to the number of doses of vaccine administered and the length of interval between the administration and the development of symptoms, since these two factors appeared to modify the illness. Group I cases received 1 ml of vaccine less than three days before onset of symptoms, Group II cases received 1 ml three or more days before onset of symptoms. Group III cases received two 1 ml doses during or overlapping their incubation period, and Group IV cases three 1 ml doses during or overlapping the incubation period. A sample case history is given for each group, and particulars of the others will be found in the Tables.

Group I Case 1

A British officer aged 34 was admitted on Nov 18, 1945, complaining of not feeling fit since inoculation with scrub typhus vaccine on Nov 12, and expressing indignation that he should have been made ill. Only slight headache had been felt on the day of inoculation. He was unwilling at this point to go to hospital but was finally persuaded to do so.

On examination an eschar was found on the scrotum, with enlarged, tender, rubbery left inguinal glands. The eschar was found to have been present since Nov 14 and was the only lesion of note. The blood pressure was 125/75 mm Hg. The white blood cells numbered 5 000 per c.mm (poly-

morphs, 52%, lymphocytes, 44%, monocytes, 4%, eosinophils, nil).

During the first week of illness he remained bright, ate well, and read technical literature, he was slightly peevish, and had

FIG 1—Group I, Case 1

a gently swinging temperature of 101°–102° F (38.3°–38.9° C) daily. No further sign appeared. On the seventh day the OX K titre was 1 80 and the blood pressure 100/60 mm Hg. In the second week the general condition remained good, he continued to sit up to eat and read, a few basal rhonchi and a slight cough appeared. Fever was now maintained at 102°–104° F (38.9°–40° C), and the OX K titre was 1 320. The spleen was one fingerbreadth increased, the liver was just palpable, and cerebation was normal. The third week brought no detectable change in his condition, apart from an appearance of tiredness, though the fever continued to swing between 101° and 104° F (38.3° and 40° C) daily. Slight insomnia was added to the headache and cough, the OX K titre was 1 1,280, and the blood pressure was 120/70 mm Hg. Deep reflexes were absent and superficial reflexes feebly present. The white cells numbered 4,200 per c.mm (polymorphs, 65%, lymphocytes, 23%, eosinophils, 12%). The spleen was one fingerbreadth increased and the liver just palpable.

Between the 22nd and 26th days of illness a few toxic signs appeared—ashen pallor with the smallest degree of cyanosis, extrasystoles, and irritability. He continued to sit up in bed and enjoyed his meals, though he found that he could read only 'light' literature. There was no loss in weight, and even after all this time he stated on questioning that he felt quite well, though he looked a shade anxious. This mild course was maintained until fever settled by lysis on the thirty-second day of illness. On the 24th day a small degree of tympanites was noted, and this persisted for three days. At the conclusion of the fever the spleen and the liver were one fingerbreadth increased. The respiratory, gastro-intestinal, and genito-urinary systems were normal. Deep reflexes were increased and the circulatory system was normal. Two months' convalescence was granted and this passed without incident.

Group II Case 9

An African aged 25 was admitted on Nov 19, 1945, giving a history of not feeling fit since Nov 17. He had been inoculated with 1 ml of scrub typhus vaccine on Nov 10. He complained of severe headache, retro-orbital and retrosternal pain, and had a slight cough with mucopurulent sputum.

On examination the throat was injected, the eyes were suffused, and a few rales and rhonchi were heard in the upper zones of both lungs. The blood pressure was 100/70 mm Hg. There was slight epigastric tenderness. An eschar was noted

FIG 2—Group II, Case 9

on the anterior wall of the left axilla, and the related lymphatic glands were greatly enlarged, rubbery, and tender. Other lymph nodes, especially the posterior cervical, were also enlarged and tender. The spleen was one fingerbreadth increased, the liver was one fingerbreadth increased and tender. No rash

as seen. Fever rose within 48 hours to 104° F (40° C) daily, never falling to normal at any time. Deep and superficial reflexes were normal. The urine was normal. The patient lay quietly in bed and had none of the usual buoyancy of the West African. The white cell count was 5,600 (polymorphs 58%, lymphocytes, 38%, monocytes, 2%, eosinophils, 2%).

During the first week all the above mentioned signs and symptoms increased in intensity. Bronchitis became severe and headache most intense. The blood pressure remained at 100/70 mm Hg, and the pulse rate did not exceed 110. He lay quietly

abnormalities noted were an eschar on the ventral surface of the penis with related groin lymphadenitis, and slight injection of the fauces. No rash was seen. The blood pressure was 110/70 mm Hg. Deep and superficial reflexes were all present and normal. The spleen was increased two fingerbreadths, the liver was just palpable. The white cell count was 6,200 (polymorphs 65%, lymphocytes, 32%, and monocytes, 3%). The OX K titre on the seventh day was 1/40. The fever swung between 101° and 103° F (38.3° and 39.4° C) daily. Throughout the illness he ate well, slept well, and sat up in bed to read, making very

B = British O = Officer I = Indian A = African. No in parentheses = Day of onset of tympanites

in bed obviously frightened. On the seventh day of illness his OX K titre was 1/40, his deep reflexes were abolished, and he was complaining of mid abdominal pain. In the second week the fever continued unabated with continuation of headache and bronchitic signs. To these was now added dyspnoea with a respiratory rate of 46 per minute. The blood pressure dropped to 95/50 mm Hg. The urinary chlorides fell to 3 g per litre. By now the spleen was increased 2½ and the liver 1½ fingerbreadths. Further complaints were of pain in the right elbow-joint and pain with swelling in both knee-joints. Acute laryngitis with complete aphonia developed, and some slight delirium with maniacal behaviour occurred, this had to be treated with intra-

little complaint of discomfort. On the 12th day of illness lysis occurred with cessation of all symptoms. On the 14th day the spleen and liver were increased one fingerbreadth, but on the 21st day the spleen was just palpable and the liver was

FIG 3—Group III, Case 13

still one fingerbreadth increased. The blood pressure on the 12th day was 100/65 mm, on the 16th day 110/70 mm, and on the 21st day 115/80 mm Hg. Deep reflexes were feeble on the 12th but were brisk by the 21st day. By the 14th day the OX K titre was 1/80. (Further results were lost in a laboratory fire.) On the 14th day the white cell count was 4,500 (polymorphs 50%, lymphocytes, 45%, monocytes, 2%, and eosinophils, 3%). Full recovery was rapid.

Group IV Case 16

An Indian Viceroy's commissioned officer aged 25 was admitted on Nov 30, 1945, complaining of slight fever, frontal headache of four days' duration. Inoculations had been given on Nov 12, 19, and 26. On examination an eschar was

FIG 4—Group IV, Case 16

muscular paraldehyde. The OX K titre was now 1/80. On the 15th day resolution started and fever settled by lysis, with sudden cessation of symptoms and gradual clearing of all physical signs. Deep reflexes returned and became exaggerated, the blood pressure rose to 110/70 mm Hg, the white cell count was 6,500 (polymorphs 46%, lymphocytes, 48%, monocytes 4%, and eosinophils 2%). The spleen and liver were palpable and two fingerbreadths increased, the OX K titre had risen to 1/320. Recovery was very rapid and he was fit for transfer to another hospital on the 18th day of illness.

Group III Case 13

An Indian aged 30 was admitted on Nov 28, 1945, complaining of slight headache and chilliness since Nov 21. He had been inoculated with 1 ml of scrub typhus vaccine on Nov 14 and 21. On examination on the seventh day of disease the only

found in the right groin with accompanying lymphadenitis. No rash was seen. The temperature on admission was swinging between 102° and 104° F (38.9° and 40° C) but immediately thereafter dropped to 99°–102° F (37.2°–38.9° C) for the next three days, followed by resolution by lysis starting by the fourth

and completely normal by the tenth day. This was the shortest fever of all 16 inoculated cases and also the shortest fever of the entire series of 130 cases. The eyes were slightly suffused, the spleen was just palpable, the liver was not palpable on the sixth day, and both were unchanged on the tenth day. All other systems were found to be normal.

On the seventh day the blood pressure was 90/65 mm and on the tenth day 95/70 mm Hg. The deep reflexes were unaltered throughout. The white cell count on the seventh day was 7000 (polymorphs, 52%, lymphocytes, 40%, monocytes, 8%). It was difficult to persuade the patient to remain in bed, since he maintained throughout that he felt perfectly fit, he ate and slept well. The Weil-Felix reaction was as follows:

7th day	OX K, 1	40	OX 19	1	80	OX 2,	nil
10th	"	1	80	"	1	80	nil
14th	"	1	160	"	1	40	nil

The blood pressure rose on the 14th day to 105/75 mm Hg. All fever, signs, and symptoms had cleared by the 12th day of illness, and the patient, at his own urgent request, was not sent to convalescence as was the normal procedure, but was returned to his unit on the 14th day, with recommendation for 10 days' excused duty."

Comment

Group I—The outstanding modifications of the usual course of the disease appeared to be (1) A considerable lengthening of the fever (average 21.5 days, as against an average for the complete series of 17.38 days and for Group II of 14.5 days) (2) A delay in the development of toxicity in some cases and its relative diminution in others. This latter was a remarkable feature in view of the long fevers (32 days in Case 1, 34 days in Case 2, and 26 days in Case 4) and the relatively high temperature reached daily $-103^{\circ}-104^{\circ}\text{F}$ ($39.4^{\circ}-40^{\circ}\text{C}$). It was odd to see all but Case 2 able to sit up in bed to read and to enjoy meals, and to find that, with the same exception, headache, retro-orbital pain and respiratory signs, when present, were minimal. Of the 16 patients, No. 2 alone showed loss of weight, and he and No. 7 both had a circulatory collapse, the former on the 21st and the latter on the 12th day. The fever was prolonged in Case 12 by a coincident amoebic hepatitis.

Group II—These cases seemed to be less affected in their general course than those of other groups. It did seem, however, that the course of the illness was probably shortened. The average length of fever in this group was 14.5 days as against 17.38 days for the entire series of 130 cases and 21.5 days in Group I. All five cases were moderately toxic; four of them showed eschars.

Group III—These two cases shared the common feature that neither patient was really ill, both sat up in bed to read and eat, and neither had any complications.

Group IV—The two cases of this group were so mild that had there not been eschars and lymphadenitis to confirm the diagnosis it would have been in doubt, especially so since the final agglutinations were lost by fire and Case 15 reached only a titre of OX K 1/80 and Case 16 1/160. Neither of these patients really felt ill at all, the fever subsiding in 10 and 9 days respectively, the former being sent to convalescence on the 16th and the latter to his unit on the 14th day.

Summary

The effect is reported of scrub typhus prophylactic vaccine on 16 patients who were at that time in the process of incubating the disease.

Of these only one (Case 2) became seriously ill; four others became ill at some stage of the disease. This compares favourably with the mortality rate of 7% for the 130 cases of 17.38 days incubated cases and the fact that of these 130 cases 10 were severely toxic.

Inoculation of 1 ml of scrub typhus prophylactic vaccine seemed to have the effect of lengthening the fever very considerably while materially reducing and delaying the onset of toxicity.

Inoculation of two doses of 1 ml produced yet milder cases, and inoculation of three 1-ml doses gave the mildest of all cases seen.

The presence of an eschar in the high proportion of 14 out of 16 cases was most helpful in diagnosis.

The general clinical features are set out in tabular form.

I wish to thank Brig Harris and Brig Macnamara, Twelfth Army, for their encouragement and for permission to publish findings, also Lieut-Col C E Moorhead and Lieut-Col P O Shea, R.A.M.C. mv commanding officers.

PROGNOSIS OF PRIMARY PLEURISY WITH EFFUSION

By

BRIAN C. THOMPSON, M.D.

late Tuberculosis Officer Middlesex County Council

Pleurisy with effusion, when its cause is otherwise in doubt, is now usually believed to be of tuberculous aetiology. It is sometimes followed by frank tuberculosis in the lungs or other organs, but the incidence of such secondary disease has never been statistically established. Published figures range from 5% (Helms, 1934) to 66% (Borelius, 1933), and a recent review by Robson (1944) shows that this wide divergence is due to three factors: (1) A clear definition is not always made between whether parenchymal tuberculosis was or was not already in evidence at the time of the initial pleurisy; indeed, many studies do not include satisfactory x-ray diagnosis. (2) Though examination of a group of patients after a period of years may show a certain proportion to have developed phthisis, it cannot establish the date of onset of such disease. This method, on which most investigators have relied, must also miss a proportion of the lesions which arise and resolve spontaneously during the intervening period. (3) Patients lost sight of must be statistically evaluated; they vitiate the results in proportion to their number, and this has generally been high.

The present study is based on 233 patients, the sum-total of all cases referred to the Ealing Chest Clinic in the years 1937-44 on account of primary pleurisy with effusion. Of these, 43 were judged to have x-ray evidence of parenchymal pulmonary tuberculosis at the outset and are therefore excluded. The remaining 190 were kept under constant observation at this clinic, with regular x-ray examination, for maximum periods up to the end of 1945, with the following exceptions: one patient was lost sight of after two and a half years, eight ceased to attend after one year and five after two years owing to removal from the district etc., but were known to be alive, well, and at work at the end of the maximum observation period. Of these 190 patients 40 have so far developed secondary tuberculosis, and six have died.

It is clear from Table I that the relative incidence of secondary tuberculosis was approximately the same in each age group and that case-fatality rates were also evenly distributed. Of the 40 patients 18 were male and 22 female. It was possible to date within a few weeks the onset of the earliest radiological evidence of a pulmonary

TABLE I—Distribution by Age and Sex

Age Groups (Years)	Cases of Pleural Effusion			No Developing Tuberculosis	Deaths

lesion, with two exceptions in which there was a lapse from observation of four years between recovery from the initial pleurisy and the detection by skiagram of parenchymal disease, these two cases are shown in Table II as developing in the fifth year

TABLE II—Annual Morbidity

Year	Total Patients	No Developing Tuberculosis in Each Year of Observation							
		1st	2nd	3rd	4th	5th	6th	7th	8th
1937	8	—	—	1	—	—	—	—	—
1938	16	2	1	—	2	—	—	—	—
1939	15	—	2	—	—	—	—	—	—
1940	22	2	4	1	1	2	—	—	—
1941	28	1	2	—	—	—	—	—	—
1942	34	5	1	—	—	—	—	—	—
1943	28	7	1	—	—	—	—	—	—
1944	39	5	—	—	—	—	—	—	—
Total	190	22	11	2	3	2	—	—	—
No exposed to risk in each successive year	190	134	102	72	45	—	—	—	—
Probability of developing tuberculosis in each year	0.12	0.08	0.02	0.04	0.01	—	—	—	—
This probability applied to basic 1 000 patients	120	70	16	32	8	—	—	—	—
No affected during each year	880	810	794	762	754	—	—	—	—
No remaining unaffected on each anniversary	—	—	—	—	—	—	—	—	—

The number exposed to risk each year is calculated by the life-table method described by Bradford Hill (1939), its several stages here being compressed for economy of space. The total 190 patients were observed for one year. The 39 originally seen in 1944 could of course not be followed beyond the end of 1945, when the survey was closed, so these must be subtracted, together with the 17 of the remainder who had already developed tuberculosis during the first year, leaving 134 at risk during the second year. A similar calculation is required in each succeeding year not forgetting the further subtraction of the one patient lost sight of in the third year of observation.

The "probability" of developing tuberculosis in any given year for those entering it so far unaffected is simply the number of cases divided by the number at risk. The two fifth-year cases, whose date of onset is unknown, must be divided by the total 190, giving a probability figure of 0.01.

The next step is to apply these probability ratios to an arbitrary total of 1,000 patients, subtracting each year the number that would become affected, leaving the remainder at risk for the following year. The progressive depletion thus taking place leaves us at the end of five years with 754 of our original 1,000 patients still unaffected. In other words, 246 have developed pulmonary or extrapulmonary tuberculosis—approximately 25%.

A similar calculation from the observed fatalities in the original series gives a death rate of 3.5% over the five-year period. This, however, is of limited value, as the

insidious and progressive character of many of the pulmonary lesions encountered leads one to expect a considerable mortality in later years.

Conclusions

Observation of 190 patients with primary pleurisy with effusion shows that one-quarter of all such patients developed systemic tuberculosis within five years. Nearly half the cases arose within one year of the initial pleurisy. No case has been found to occur after five years.

Of the tuberculous lesions that developed 15% were extrapulmonary. The remainder first became evident in the lung, though in either case spread to other systems tended to occur, as in any similar lesion acquired in other ways.

The death rate for the five-year period was 3.5%.

The age of the patient did not seem to influence either the incidence or the character of any subsequent tuberculosis.

A CASE OF BILATERAL SIMULTANEOUS SPONTANEOUS PNEUMOTHORAX

BY

GEORGE M. KOMROWER, M.B., M.R.C.P.

Late Officer in Charge Medical Division British General Hospital

Bilateral simultaneous spontaneous pneumothorax is relatively uncommon (Glickman and Schlomovitz in 1939 reported only 82 cases in the literature) and is often fatal. The following case is presented because of the rapid uninterrupted recovery and the methods employed to reduce the dangerous positive pleural pressures.

Case Report

A soldier was admitted to hospital on Nov. 28, 1944 with the following history. He awoke that day with a slight pain in the right chest, not associated with cough or dyspnoea but these symptoms became well established when he began his daily duties, and in the afternoon he reported to the outpatient department, where a spontaneous pneumothorax was discovered. Inquiry into his family and previous medical history revealed nothing of significance.

On examination he was seen to be a well built healthy individual with little cyanosis and no dyspnoea when at rest. His trachea was displaced to the left, and his apex beat was located 1 in. (2.5 cm.) external to the mid-clavicular line. There was diminished movement of the right chest, the percussion note was more resonant on the right side, and breath sounds were diminished in the right lung. X-ray examination confirmed the diagnosis of a complete right pneumothorax and he was ordered complete bed rest. On Nov. 30, when using a bed-pan he experienced a sudden pain in the left chest and rapidly became extremely cyanosed and dyspnoeic. Examination revealed the presence of a bilateral pneumothorax and efforts were immediately made to relieve the man's respiratory embarrassment. His intrapleural pressures were right + 7 → + 8 left + 3 → + 6, after the removal of 1,200 c.c. of air from each pleural cavity they became, right, - 3 → + 4, left - 3 → + 4. His general condition improved for a short time but his cyanosis and extreme dyspnoea

returned, and decompression was again carried out in the early evening a further 1,200 ml being removed from each pleural cavity.

Whilst considering how we might best leave him for the night, our radiologist Capt Tomlinson, produced an article by Major H Fuld (1944) describing a simple device for the control of tension pneumothorax. It was decided to try this method of decompression and a modified French blood transfusion needle which passed through the centre of a rubber diaphragm was inserted into each second intercostal space close to the sternum. Each needle was connected to a one way outlet valve of a standard transfusion apparatus which permitted only the egress of air. These in their turn were connected to short lengths of rubber tubing which were strapped to the chest wall. The man's general condition improved considerably until the early morning when the needles slipped a little and became blocked, necessitating clearance with a stylet and readjustment. As a result he developed emphysema of the chest wall neck, and face. On Dec 1 the needles were removed and reinserted in the fifth intercostal spaces in the anterior axillary line, and in the afternoon the intrapleural pressures were right, 0 → 2, left, 0 → - 2.

The needles were finally removed the next day, as there was no cyanosis or dyspnoea, and a course of sulphadiazine (30 g in all) was started—it was thought that he might develop an infected effusion as a result of the repeated needlings. However, he made an uninterrupted recovery from this date, his lungs expanded steadily, there was no pleural effusion, and the emphysema subsided. By Dec 10, ten days after the onset of symptoms his lungs had almost completely re-expanded and he was evacuated to England by hospital ship.

Unfortunately the photographic copies of the x-ray films are very indifferent and would not bear reproduction. The first film, taken soon after the left lung collapsed, showed a small nodule of lung at each hilum surrounded by air. There were no adhesions and no mediastinal shift. Both lungs expanded evenly, but the left side eventually lagged a little behind the right, and when the patient was evacuated the right lung had expanded completely.

Discussion

The literature lays great stress on the frequency of evolutive pulmonary tuberculosis in the causation of bilateral spontaneous pneumothorax, McMahon (1932) giving a mortality rate of 58%, compared with 16% due to emphysema. Glickman and Schlomovitz (1936) in their review of 82 cases (fatal and non fatal) state that 38% were tuberculous, 12.5% were due to emphysema, and 21% were in the idiopathic group, pneumoconiosis, congenital cysts, bronchopneumonia, and tumours accounted for the remainder. Emphysema was found to be the cause of death in the cases recorded by Meyer (1917), Werner and Thearle (1942) and King and Benson (1944).

Olbrechts (1920) divided the bilateral condition into simultaneous and successive in the former both lungs collapse at the same time or one follows the other before the air has been absorbed. In discussing the aetiology he suggests that it is either a coincidence or an anatomical disposition (congenital or acquired) which leads to an added fragility of the surface of the lungs. Le Wald (1926) suggested the passage of air from the right to the left pleural cavity across an office in the mediastinum and commented on the occasional fistulization of the mediastinum in the course of a therapeutic pneumothorax. This theory was also mentioned by Bedford and Joules (1929) who suggested that it might explain the fact that they aspirated only one side of the chest, with complete recovery. The prognosis is very poor in tuberculous cases and is little better in emphysema whereas the idiopathic cases may make a complete recovery.

There is no evidence of tuberculosis, emphysema, pneumoconiosis or lung infection in my case, and it would appear to come into the "idiopathic" group. In order to

prevent a recurrence the patient was sent home to England, for consideration of the artificial production of adhesions. In considering the conduct of the case it should be remembered that the needles must be long enough to pass into the pleural cavity in comfort and so obviate the possibility of surgical emphysema, that it is not necessary to take the rubber tubing under water (thus allowing greater nursing freedom), and that it is safer to check the pressures at regular intervals in order to determine the progress of the condition and the amounts of air to be removed. Finally, sulphadiazine was given prophylactically, but it is impossible to state whether it had any beneficial influence on the uncomplicated recovery.

Summary

A case of bilateral simultaneous pneumothorax is presented, with a description of the method employed in an endeavour to overcome the tension pneumothoraces.

The literature has been reviewed from the point of view of aetiology and of prognosis, and the suggestion is made that the case falls into the "idiopathic" group, in which the outlook is reasonably good.

I wish to thank Major W. R. Trotter, R.A.M.C., and Capt. M. N. Tomlinson, R.A.M.C., for their assistance, and Col. R. W. Savage for his permission to publish this case report.

Medical Memoranda

End-Result of Colectomy for a Case of Chronic Constipation

The following is a report of a case of chronic constipation due to lack of tone in the musculature of the large bowel. After extensive medical measures had been tried unsuccessfully, colectomy, with implantation of the ileum into the lower third of the pelvic colon, cured the constipation and produced great improvement in the mental and physical health of the patient.

CASE REPORT

In January, 1940, a young man of 21 came to me with intractable constipation. He was thin, sallow in complexion, and very worried. He had consulted many doctors in the past four years without success and if nothing further could be done he said he would take steps to end his life. He had been treated by massage, daily enemas, and colour wash-outs, diet, liquid paraffin and other drugs, physical exercises, and suggestive treatment. Nothing had helped him and heroic doses of purgatives and violent exercise were necessary to get his bowels to act as often as once a week. As the days went by without a bowel action he developed persistent headaches, an increasing feeling of lassitude, and complete anorexia. His chemist's bills were getting him down, and he considered that if he had to spend so much of his day for the rest of his life endeavouring to get an action of his bowels, life would not be worth living. He was very pessimistic about the outcome of his visit to me and his case seemed most unpromising. His past history was negative, no serious illnesses, no history of dysentery or excessive constipation as a child. He was fond of exercise, chiefly walking, tennis and riding. He had been fit and healthy until four years before, when constipation of increasing severity began to trouble him.

Examination showed him to be much under weight, with a dry, red, shiny skin. His tongue was furred. The abdomen was normal except for many borborygmi. Reflexes were normal, and the

ohr and Wassermann reactions negative X ray examination disclosed great delay, chiefly in the ascending and transverse colons, and a barium enema ran easily back to the caecum, causing huge dilatation of the whole large bowel The blood, urine, and faeces showed no abnormality In view of his mental state and realizing the futility of further medical treatment, I decided to operate

Laparotomy was performed on Jan 20, 1940 There were no adhesions or bands, and the only pathological feature was a slightly dilated extremely mobile colon The dilatation was most pronounced in the ascending and transverse colons, and beyond the splenic flexure the gut was empty and collapsed There was a remarkable lack of tone throughout the whole of the large bowel

It seemed possible that some kinking was occurring at the splenic flexure owing to the abnormal mobility, and accordingly an anastomosis was made between the transverse and descending colons The patient made a good recovery His defeatist outlook was jolted when he passed a daily motion with the aid of liquid paraffin only, from the seventh day onwards He left hospital on the twenty first day after operation considerably cheered, but firmly convinced that he would soon return to his former state—and he did!

Four months later he returned as depressed and as constipated as ever I reopened his abdomen on May 24 The caecum and all the large bowel down to the centre of the pelvic colon were removed, and the ileum was anastomosed to the lower end of the pelvic colon He made a good recovery, and liquid stools were passed daily, with out medicine, from the fifth day after operation He was discharged from hospital on June 25, feeling well, and passing one or two liquid stools a day His mental outlook, despite encouragement, was still poor, he felt certain that the old trouble would reassert itself before long He was then transferred to a small out station, and I heard nothing more from him until June 6, 1944, when I received a letter, part of which I quote "I am pleased to say that I am now in perfect health I am sure you would not recognize me now as I have grown quite fat My health seems to improve every day, and I am not taking any medicine at all, a little brown bread is all I need if I get at all constipated The last operation seems to have been a wonderful success"

The pathology of the bowel in this case is not clear The small intestine was slightly dilated and thickened, but in the colon there was no hypertrophy of the muscular coat or thickening of the mucosa as seen in Hirschsprungs disease or megacolon There appeared to be a lack of tone in the musculature which allowed the bowel to distend to a great size without causing either pain or peristaltic movements

Three Cases of Agranulocytosis

In view of the report by Drs Librach and Cronin of a case of primary agranulocytic angina (*Journal* Dec 14 1946, p 897) I am prompted to publish notes of three cases of agranulocytosis in British prisoners of war in Singapore

CASE REPORTS

Case 1—A medical officer of the IMS—a personal friend—aged about 35 was in good health, so far as the diet and conditions allowed, at the time of the onset of his illness He had suffered from 'painful feet' the previous year, which had been greatly relieved by injections of "nicamide" In April, 1944 a further series of injections of nicamide had been given for an increase in these pains On May 7, 1944, he had noticed tenderness of his jaws and teeth, and during the night had had several attacks of shivering followed by sweats Next morning he was admitted to hospital The temperature was 103° F (39.4° C) and it continued at about this level until May 13 The only physical finding on admission, apart from the pyrexia, was tenderness and slight enlargement of the neck glands Repeated blood slides were negative for malaria parasites The white blood cell counts were as follows

Date	Total per c mm	N Poly morphs %	Lympho cytes %	Mono nuclear %	Myelo cytes %	Myelo blasts %	Other Cells %
May 8	4 600	2	76	12	—	—	10
10	3 600	0	89	6	5	—	—
11	2 900	7	71	8	6	2	6
13	8 400	32	58	5	5	—	—
16	12 800	41	30	3	17	2	7

The tenderness of the jaws developed into severe pain, which necessitated repeated injections of morphine for the next 48 hours On May 9 he was given 4 ml of liver extract and 10 ml of 'pent-nucleotide' Next day these doses were repeated Three sloughs

had now appeared on the gums A course of sulphapyridine was started, 5 g being given on the first day and 3 g the next day No further liver, pentnucleotide or sulphapyridine was given, as the blood counts showed a gradual improvement Fragments of alveolar margin separated during his convalescence which was otherwise uneventful

Case 2—An assistant surgeon aged about 35 was taken ill with fever and general malaise on April 6 1944 Between April 6 and 13 repeated blood slides proved negative for malaria parasites, stools were negative for amoebae, and a blood count was normal When seen on April 13, the eighth day of illness, he presented a flushed dry skin, suffusion of the eyes, injection of the throat, and a temperature of 104° F (40° C) There were several small superficial crusted sores on his legs, buttocks, and hands, and a moderate degree of axillary and inguinal adenitis The white blood cell counts were as follows

Date	Total per c mm	N Poly morphs %	Lympho cytes %	Mono nuclear %	Myelo cytes %	Myelo blasts %	Other Cells %
April 13	3 000	23	71	4	—	—	2
14	3 200	5	86	8	—	—	1
16	2 400	10	81	8	1	—	—
18	4 200	38	51	6	5	—	—
20	9 000	77	19	2	—	—	2
24	13 000	77	—	—	—	—	—
26	11 000	66	—	—	—	—	—
May 12	5 200	66	—	—	—	—	—

The pyrexia continued at a high level for some days after sulphapyridine treatment was started on April 15, 18 g being given in six days The pyrexia did not settle finally until May 12

Case 3—A staff-sergeant aged about 35 had had an area of eczema on the left leg for 2½ years He noted that the lesion was spreading, and reported for treatment on March 25, 1945 On April 10 he developed a pyrexia of 100 F (37.8 C) and complained of pain at the site of the eczema Routine blood slides were negative for malaria parasites I saw him the next day His temperature had risen without remission to 104° F (40° C) He was very cheerful and mentally alert In the patch of eczema on the left lower leg were three small seabs which were tender to pressure The inguinal glands on that side were slightly tender and enlarged The white blood cell counts were as follows

Date	Total per c mm	N Poly morphs %	Lympho cytes %	Mono nuclear %	Myelo cytes %	Myelo blasts %	Other Cells %
April 10	3 200	1	89	—	10	—	—
12	2 000	14	70	2	14	—	—
13	1 800	40	39	—	—	—	—
16	3 800	59	33	—	8	—	—

On April 11 treatment with sulphapyridine was started, 22 g being given by April 14 Pentnucleotide was not available, and the only specific drug, sodium nucleinate, was exhausted after injections of 5 ml and 3 ml on successive days The fever gradually abated and was normal by April 17, when there were signs of necrosis of the skin, fluctuation under the skin of the eczematous area, and lymphangitis spreading up the leg and thigh He was transferred to our surgical colleagues who then assisted his return to health

DISCUSSION

Many cases of agranulocytosis can be attributed to recognized poisons—organic, inorganic, and bacterial Various other causes are cited as being responsible, including nutritional deficiency The latter was a common factor to all three cases and infection was a common factor to Cases 2 and 3 Despite the thousands of cases of uncomplicated nutritional deficiency which were seen, Case 1 was the only example of agranulocytosis, and I feel inclined to regard it as one of primary agranulocytosis

An annotation in the *Journal* of Dec 14 1946 (p 905) gives a brief resumé of the treatment of agranulocytosis No whole-hearted support is given to any particular method of stimulating leucopoiesis As no certain line of treatment is available for this grave condition, the physician in charge feels bound to use nucleic acid in some form and liver extract, penicillin or one of the sulphonamides is given to counteract the infection which follows in the course of the disease When infection appears to be the causative factor, these latter drugs take place in treatment

OLD AGE

The Care of the Aged (Geriatrics) By Malford W. Thewlis, M.D. Fifth edition. (Pp 500, 65 illustrations 40s.) London: Henry Kimpton 1946.

Dr Thewlis approaches the problem of the treatment and care of old people in a practical way. He realizes that prompt attention to what may appear, in younger persons to be trivial conditions will, in old persons prevent them from developing rapidly into serious, and even untreatable, illness. In his detailed chapters on treatment Dr Thewlis emphasizes that the old respond well provided that treatment is well planned and undertaken early. It is important, too, that physicians should appreciate the difference between the normal physiological processes associated with an ageing person and those changes which are evidence of senility—a process which displays the infirmities of the aged.

While functional changes due to senescence are inevitable, they are no more peculiar than are those changes that occur when an infant develops into a mature adult. The recognition of this fact leads the author to the natural conclusion that it is important for anyone who has medical charge of old persons to make sure that they are encouraged to continue a normal and active life for as long as they are physically or mentally able. The old enjoy working and taking a full part in life, and they have shown that they are capable of a valuable contribution to their country's wealth; they should therefore be encouraged to this end. That much can be done to delay or prevent what are often considered the natural concomitants of old age Dr Thewlis gives ample proof. A study of his wise appreciation of the difficulties both mental and physical, of old age will do much to improve the lot of the aged in all walks of life. Particularly his contention that the problems of geriatrics are those of medicine generally and not those of a special separate branch.

AMULREE

PSYCHO-ANALYSIS OF CHILDREN

The Psycho-Analytical Treatment of Children By Anna Freud. Technical Lectures and Essays. Parts I and II translated from the German by Nancy Procter Greig. (Pp 98 10s 6d.) London: Imago Publishing Co. Ltd. 1946.

These collected essays of Anna Freud are of a highly technical nature but none the less interesting and welcome. The first part consists of four lectures now belatedly published in this country since they did not previously find favour with British analysts in whose eyes the theories and work of Mrs Melanie Klein found more acceptance. Miss Freud considers Mrs Klein's play technique too objective, leaving too much to the interpretations of the analyst. Her own technique consists of establishing an alliance with the child in the introductory phase of treatment if necessary against the parents, whose good will she must retain and assuring the young patient that the 'devil' which is within him and which he consciously recognizes can be exterminated with the help of the analyst. The latter must have to identify herself with all the patient's tastes and tastes and become not only interesting but useful to him even to the extent of protecting him from punishment for his misdeeds. The transference situation having once been established the patient can then be required to surrender all his secrets. This is helped by the game of interpreting dreams of the night but day dreams as well—which often to the father can be made to take the form of a play. Free associations are difficult to obtain from the child but the analyst may come to be foretelling but the child's associations are considered to be equivalent to the free associations of the adult. However the child unlike the adult cannot go back to a transference neurosis since in the child's mind the ego cannot reproduce and live through its past. For these reasons child analysis is not a method for the problems of adult life. The child is concerned with the very early years of life and the analyst must be prepared to remember the early years of life before the acquisition of speech.

are not available. The adult, once the roots of the neurosis are disclosed, can readjust his life if he wishes on his own initiative, but the child cannot do this, and he therefore requires the help of the analyst to educate him and construct his character as well as to do what he can to modify the environment of the child so as to make his adjustment easier.

These preliminary lectures are the basis for the second and third parts of the book dealing with the theory of child analysis and the indications for it. The latter, the author thinks, are concerned with abnormalities of development rather than with frank clinical neurotic illnesses, and she points out that we know all too little about these faults of development and that the gaps in our knowledge can be filled only by painstaking analyses of individual children. Students of child psychiatry who are not members of the psycho-analytical school should not be put off by the technical presentation of lectures delivered to psychoanalysts, for a careful perusal of them will provide much which is both interesting and instructive.

R G GORDON

AN X-RAY PRIMER

The Osseous System. A Handbook of Roentgen Diagnosis By Vincent W. Archer, M.D. (Pp 320 illustrated 55 50 or 33s.) Chicago: The Year Book Publishers. London: H K Lewis and Co.

The preface of this book begins with the statement that it is written for and is dedicated to the occasional radiographer. From the text it is evident that this means not a technician but the doctor who, without being a radiological consultant, is called upon at times to attempt x-ray diagnosis. As the author says, the book is a primer rather than an encyclopaedia, and the text is sketchy. It is extensively illustrated, with 150 plates comprising 300 to 400 illustrations. The volume might be regarded as an unusually well annotated x-ray atlas. The technique of radiography is not discussed. The illustrations are varied and cover the field well considering the scope of the work, but in some cases the double transposition back to the negative has resulted in loss of essential detail.

The book has four sections—introductory, skeletal injuries, bone diseases in children, and bone diseases in adults. Of these the section on injuries will be found the most useful, and a wide variety of fractures and diseases are described. The section on bone diseases is arranged not on a pathological basis but with reference to the salient radiological feature. An excellent index makes it easy to refer to any particular disease in the text. This should be a useful handbook for both clinician and radiologist—to the latter chiefly because of the admirable illustrations of many unusual conditions.

LECTURES ON SCHIZOPHRENIA

The Biology of Schizophrenia By R G Hoskins Ph.D. M.D. (Pp 192 15s.) London: Chapman and Hall 1946.

This book is an extended version of the Salmon lectures given last year by Dr Hoskins. He is the Director of Research at the Worcester State Hospital, where over the past twenty years and more a large amount of work has been done on disturbances of bodily function in schizophrenia. These lectures summarize the work and forecast the trend of future research. Positive findings have not been lacking; they are practically all of the statistical type—that is schizophrenics as a whole differ from normal persons to a significant degree in a great number of measurements. There are suggestions of deficiency in most endocrine functions—thyroid, adrenal, pituitary, and gonad. Treatment with various glandular preparations has been tried with very disappointing results. There are differences in basal metabolic rate in metabolism of sugar and glutathione, and also in the circulatory system as shown in blood pressure, pulse rate and circulation rate. But there is no qualitative difference between the schizophrenics and normal persons.

In this respect Dr Hoskins and his co-workers have been regularly unfortunate. It may be remembered that Gessing, in Norway, has found in schizophrenics with circulatory recurring phases remarkable disturbances of nitrogen metabolism to a large extent controlled with thyroid, and that Hemphill and Reiss in this country, have found specific pathological changes

in the seminiferous tubules in quite early cases of schizophrenia. The work in America has led to no coherent theoretical interpretation, we are left with a jigsaw puzzle as apparently meaningless as ever. The one general finding, which repeats itself over a large number of functions, is that schizophrenics are less reactive than the normal, they can even stand much higher levels of physiological stress. One test, which involved breathing warmed moist oxygen, caused collapse in a quarter of the normal controls but was survived by the schizophrenics without notable distress.

Dr Hoskins alienates the reader by devoting two out of his three lectures to general considerations without much relevance or interest and by a style which is stilted, pompous, and sometimes absurd. "It is a well known apparent paradox that preceding acrimony enhances the vividness of connubial empathy." The book's principal fault is that figures and tables are generally eschewed, for these the worker, who might otherwise have found it invaluable as a convenient source of reference, must turn to the original papers given in the bibliography. A disappointing inconclusiveness pervades this work.

ELIOT SLATER.

BACTERIAL ADAPTATION

The Chemical Kinetics of the Bacterial Cell By C. N. Hinshelwood, F.R.S. (Pp 284, 79 figures and one plate 20s.) Oxford Clarendon Press 1946

This is a rarity among scientific works, for it is neither a textbook nor a comprehensive monograph. It is a reflective book—the author himself calls it an essay—in which he has brought together certain concepts of physical chemistry and selected data (mostly his own) on bacterial growth and adaptation in order, as he says, to see what the composition looks like. The adaptation of bacteria to drugs and to new sources of nutriment is of such intrinsic interest for the study of cell processes, apart from its medical importance, that the reflections of a distinguished physical chemist who has been applying the methods and concepts of his own subject to it for some ten years are something of an event. The author regards adaptation of bacterial cells as an automatic response to an altered environment: changed reaction velocities, resulting from the inhibition of one or more enzymic processes, lead to the establishment of new enzyme balances, either in the sense that the proportion of an inhibited enzyme to other enzymes is altered or that alternative enzymic routes which in the unadapted cell were relatively unimportant, come to play a major role. These ideas are applied quantitatively and with relatively simple mathematical treatment, to such phenomena as lag, growth rate, reversion, and cross adaptation. The influence of natural selection, though it is not regarded as the primary factor, must be superimposed upon other adaptive mechanisms.

Underlying these ideas is an original conception of how enzymes increase in amount in the growing cell, by analogy with some inorganic catalytic reactions it is suggested that enzymes increase their substance by removing suitable protein fragments from substrate molecules, leaving residues which act as intermediates in further enzymic reactions, thus enzyme + substrate = expanded enzyme + intermediate. The initiation of this process is thought to be due to the attraction which an established protein pattern must exert on protein fragments of like constitution, just as a crystal facilitates crystallization from a solution by providing a lattice on which fresh molecules can orient themselves. This conception of an autolytic process is illuminating from several points of view: it obviously links up with the ideas of Fildes and Woods on what have come to be called metabolic antagonists, also established protein patterns are seen to be the inheritance which daughter cells receive from their parent. The book abounds in suggestive ideas, and tribute must be paid to the skill and economy with which the author has presented his reflections, one reader at least has derived both aesthetic pleasure and intellectual excitement from its perusal.

H. R. ING

A Primer for Diabetic Patients (8th edition W. B. Saunders 9s.), by Russell M. Wilder, M.D., F.A.C.P. contains the substance of the instruction given to patients in the diabetic school of the Mayo Clinic. A list of questions to test the patient's knowledge follows each chapter.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

A Synopsis of Anaesthesia By J. Alfred Lee M.R.C.S. L.R.C.P., M.M.S.A., D.A. (Pp 254 12s 6d) London Simpkin Marshall 1947

Designed as a summary of current teaching and practice for the student, house man, and practitioner. Includes chapters on the use of curare, complications of anaesthesia, and shock.

Biochemistry of Cancer By J. P. Greenstein Ph.D. (Pp 389 \$7 80) New York Academic Press 1947

Includes sections on the induction of tumours, attempts at control of tumour induction and of tumour growth and the properties of tumours.

Radiology for Medical Students By F. J. Hodges, M.D., I. Lampe, M.D., and J. F. Holt, M.D. (Pp 424 37s 6d) London H. K. Lewis 1947

An American outline of the use of x-rays for diagnosis and therapy, intended for medical students, many diagrams reproduced.

Diagnostic Neuro-Surgical By J. Guillaume and J. Sigwald. (Pp 457 500 francs) Paris Presses Universitaires 1947

After discussing the anatomy and physiology of the brain the authors describe the various cerebral neoplasms. Chapters on the investigation of the brain and spinal cord follow.

The Anatomy of the Nervous System 8th ed. By S. W. Ranson, M.D., Ph.D., revised by S. L. Clark, M.D. Ph.D. (Pp 332 32s 6d) London W. B. Saunders 1947

This profusely illustrated American textbook has been rewritten in parts and new material added, gross descriptive anatomy is now included in one section.

Dimensions of Personality By H. J. Eysenck, Ph.D. et al. (Pp 308 25s) London Kegan Paul, Trench, Trubner 1947

A team of psychologists and psychiatrists has examined 10,000 normal and neurotic subjects in an endeavour to define the dimensions of the personality by means of quantitative procedures.

An Integrated Practice of Medicine By H. T. Hyman M.D. 4 vols and index (Pp 4,131 £12 10s) London W. B. Saunders 1946

This American work is designed for the general practitioner. Includes new colour photographs and 318 tables of differential diagnosis.

The Rhesus Factor By G. Fulton Roberts, M.A., M.B. (Pp 47 3s 6d) London William Heinemann Medical Books 1947

An account in simple terms of the rhesus factor, with illustrative case histories and a chapter on the treatment of its effects.

Introduction à la Criminologie 2nd ed. Vol. I. By Dr E. G. Greeff. (Pp 414 No price) Brussels Duculot 1947

After a chapter on the criminal's environment the author discusses his anatomy, physiology, and personality. There is a concluding chapter on homicide.

A Psychology of Growth By B. I. Beverly, M.D. (Pp 214 12s 6d) London McGraw-Hill Book Company 1947

An account of mental development from infancy to adolescence intended primarily for the instruction of nurses.

Ego, Hunger and Aggression By F. S. Perls, M.D. (Pp 112 12s 6d) London George Allen and Unwin 1947

The author, a practising psychoanalyst, criticizes orthodox psychoanalysis and introduces semantics and holism. Intended for general practitioners as well as psychiatrists.

Gynaecological and Obstetrical Pathology 2nd ed. By E. Novak, A.B. M.D., F.A.C.S. (Pp 570 37s 6d) Philadelphia and London W. B. Saunders 1947

The author has revised the text in this edition and added over 100 new illustrations, some in colour.

Diseases of the Skin 5th ed. By J. H. Sequeira, M.D., F.R.C.P., F.R.C.S., J. T. Ingram, M.D., F.R.C.P., and R. T. B. M.D., F.R.C.P. (Pp 782 63s) London J. and A. Churchill 1947

This edition includes new material on chemotherapy, industrial dermatoses and tropical diseases. Many illustrations, some in colour.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY APRIL 12 1947

VAGINAL PLASTIC OPERATIONS

Prolapse of the uterus and vaginal walls is so common that it is fortunate that the results of its surgical treatment are, on the whole, satisfactory. Plastic operations on the vaginal wall date back to 1831, when they were first suggested by Marshall Hall, of London, but the Manchester school—A. Donald, W. E. Fothergill, and their followers—has played a leading part in the development of present-day surgical procedures for the cure of genital prolapse. Many modifications of the "Manchester operation" are practised, but all follow the same fundamental principle of strengthening the natural supports "from below." It can be applied to every case of prolapse irrespective of degree and type, and a cure rate of over 95% is recorded both in this country (Fletcher Shaw¹) and in the U.S.A. (Maier and Thudium,² and Gordon³). However, it is not so successful in the hands of all surgeons, and individual skill, judgment, and experience count much when the end results are assessed. The Manchester operation has never found elsewhere such general favour as it has in the North Country, and its enthusiastic advocates have sometimes suggested that this is not always the fault of the operation itself. In America, in particular, various other procedures such as the Watkins interposition operation and vaginal hysterectomy are preferred, especially for gross degrees of cystocele and of uterine prolapse.

Vaginal hysterectomy is an operation of considerable antiquity—apparently performed as long ago as the second century A.D.—and procidentia was its indication in some of the earliest recorded cases.⁴ That it has a place in the treatment of uterine prolapse would now be admitted by nearly all gynaecologists, though the importance of the place might be disputed. Wilfred Shaw, in this issue of the *Journal*, expresses a preference for it in cases of severe prolapse in post-menopausal women, and also when the uterus is diseased as well as displaced. Provided there is no uterine disease many would restrict the use of vaginal hysterectomy to those cases in which the pelvic pouches of peritoneum lie low, and those in which the uterus remains small and its descent is associated with inversion of the vaginal vault. Complete prolapse of the uterus is not common, and in many cases the degree of descent is less than appears at first sight, the protruding mass being mostly in oedematous, hypertrophied, and elongated cervix. For

such the need for vaginal hysterectomy is open to question. Gordon³ has recently recorded 26 consecutive cases of third-degree uterine prolapse successfully treated by the Manchester operation.

The traditional objection to removal of the uterus is that it removes the "keystone from the arch," and that this is followed by prolapse of the vaginal vault, which then becomes exceedingly difficult to correct. If this is to be avoided the supports of the upper vagina must be strengthened during the course of the operation. In vaginal hysterectomy by the clamp method⁴ this is not done but the good results claimed may be due to the fibrosis which follows when the tissues at the vault heal by secondary intention. In the Mayo technique the cardinal ligaments are brought together to form a strong roof. Some stitch the utero-sacral ligaments to the pubo-cervical fascia in front. Wilfred Shaw suggests attaching the anterior leaf of peritoneum and the upper broad ligament pedicles to the "post-urethral ligament" to provide a better support for the bladder. Recurrent prolapse after vaginal hysterectomy, however, is more often enterocele than cystocele and obliteration of any hernia of the pouch of Douglas is perhaps the more important step in the operation.

One of the symptoms of cystocele and urethrocele and one which is the most difficult to cure is "stress incontinence" of urine—a descriptive term coined by Sir Eardley Holland. All sorts of plastic operations on the tissues deep to the anterior vaginal wall are carried out with the object of tightening urethral sphincters and of supporting the bladder base and urethra and of restoring them to normal position, but in only about 60–80% of cases are they completely successful (Studdiford⁵ and Aldridge⁶). The most difficult cases are often those in which the amount of cystocele is negligible. The result of anterior colporrhaphy may be anatomically perfect, yet bladder control remains impaired, indeed sometimes it appears to be worse. The treatment of this distressing symptom remains a problem, mainly because the anatomy and physiology of the female urethra and bladder neck and the mechanism of micturition are not understood.

Wilfred Shaw now gives a new description of the arrangement of fascia and ligaments deep to the anterior vaginal wall and includes new names for anatomical features which, as he points out, must be familiar to many gynaecologists. The value of this may depend ultimately on the significance of the fibromuscular fascia beneath the urethra which he calls the post-urethral ligament, and on whether by suturing this to the uterus it is possible to cure more cases of stress incontinence. Shaw's technique appears to offer a means of elongating the urethra and for putting the internal meatus as far back in the pelvis as possible. X-ray visualization of the normal urethra and bladder suggests that this is anatomically sounder than attempts to buttress the urethra up to the back of the symphysis pubis.

The complexities of the problem are illustrated by the fact that whereas Shaw describes the post-urethral ligament as stretching between the two inferior pubic rami, and emphasizes that this pubic attachment should not be

¹ *Amer. J. Obstet. Gynec.*, 1933 25 667² *Ibid.*, 1932 24 248³ *Ibid.*, 1946 52 228⁴ Kennedy J. W., and Campbell A. D., *Vaginal Hysterectomy*, 1942, A. Davis, Philadelphia⁵ *Amer. J. Obstet. Gynec.*, 1945 50 119⁶ *Ibid.*, 1946 51 299

disturbed, Kennedy,⁷ who describes an involuntary urethral sphincter and a voluntary "muscle of micturition" in this area, insists on the necessity for separating any adhesions between the peri-urethral tissues and the pelvic bones if stress incontinence is to be cured. He is supported by Counsellor,⁸ who cured 26 consecutive cases of urethral incontinence by the Kennedy operation. Again, in the "fascial sling" operation of Aldridge⁹ the tissues at the side of the urethra are deliberately separated from the pubic ramus in order to bring down the fascial strips, yet so far there is general agreement that this operation and others similar in type usually restore urethral control when all other measures have failed. The insertion of fascial and muscle transplants deep to the anterior vaginal wall has developed gradually during the course of about forty years. The object is to support the urethra and bladder neck with healthy tissues from another site rather than with the local tissues, which may be overstretched, denervated, and damaged irretrievably. Pieces of gracilis, pyramidalis, levator ani, and bulbocavernosus muscles, and of fascia lata, have all been used. The operation increasingly practised to-day is one whose origin can be traced back to Goebell,¹⁰ who in 1910 turned down the pyramidalis muscles and attached them to the neck of the bladder. Of the subsequent modifications an important one was introduced by Stoeckel,¹¹ who combined the operation with a repair of the vaginal wall. The technique mostly used now is that of Aldridge,⁹ and in this strips of the oblique muscles of the abdominal wall are passed behind the symphysis pubis to form a sling round the urethra, the latter being further supported by anterior colporrhaphy. A few prefer not to open the vaginal wall but to pass the strips from above after dissection of the space of Retzius. Operations of this kind have, as yet, had only a limited trial, but they promise well. It is unwise, however, to make too early a claim for a cure of urethral incontinence by any operation. Relapse of symptoms within a few months of an apparent cure is common, and an interval of not less than two years between treatment and the assessment of the result is desirable.

For stress incontinence, as for uterine and vaginal prolapse, many operative procedures are available, and each surgeon tends naturally to adopt the one with which he is most familiar and, if need be, to modify it to suit individual cases. There is always a danger, however, of loyalty to one operation leading to prejudice. It is becoming increasingly clear that cases of prolapse vary considerably, not only in type but in aetiology. The same is almost certainly true for urethral sphincter incompetence. An "all purpose" operation is not the best for all cases, and "the most successful surgeon in the cure of genital prolapse will be he who, with a wide knowledge of all the methods at his command, chooses the one which will be best suited in individual cases" (Gray Ward¹²). Wilfred Shaw's important contribution to the subject will be widely studied and will induce many gynaecologists to review their own procedures in the light of what he says.

HEALTH EDUCATION

The ordinary citizen is slow to associate education with health. He accepts schooling as a matter of course to fit him for membership of a literate community, and technical and professional education as a means of earning a livelihood, he is prepared for arduous lessons in order to acquire some incidental accomplishment, such as playing a piano or driving a car. But he has an idea that such health knowledge as he needs "comes natural," though health is a prime condition of success in all these other ventures. He is usually content with his state of being not ill, should he fall below the level of not-illness—well, what is the medical profession for? The term "positive health" is of recent use, and to many people means little or nothing. There is also squeamishness on this subject. Many matters connected with health are thought to be too indelicate for mention in polite company, not the sort of thing for education. Only a few years ago most of the national news papers, which very closely reflect the conventional proprieties, declined advertisements which advised people to wash their hands after defaecation. It was not until 1947 that venereal disease was mentioned, except allusively, in a broadcast.

The war gave point and urgency to health education, and also accustomed people to methods of mass publicity which in other days would have offended or merely amused as many as they informed. The Central Council for Health Education, a very forthright body, came on the scene like a brisk housekeeper entering a shut-up room, opening the windows and vigorously dispelling the dust and cobwebs. Every instrument in the publicity orchestra—the phrase is that of the Public Relations Officer of the Ministry of Health—was used to get health facts and counsel across to the public: the film, with the trailer after the news reel, the leaflet, the poster, articles and advertisements in the Press, lectures, pictorial exhibitions, and, most wide-ranging of all in its appeal, the broadcast. The campaign for immunization against diphtheria was an example of well-directed teaching towards the prevention of one of the principal killing diseases of childhood, and it illustrated, too, how excellently central and local efforts could be combined. Another method widely adopted during the war was the Press conference. The periodical conferences held by the Chief Medical Officer of the Ministry of Health when forty or fifty Press representatives would gather round the table to hear his commentary and to ask questions, were of great value in making the public acquainted with the facts of the public health or the epidemiological situation, getting precautionary measures accepted, and nipping false rumours in the bud. There was the usual "hand-out" of documents, so that the journalist could be sure of his facts, but the method did enable him to put his individual style into a subject which presently became as "live" as politics. The Press conference has been adopted by many health and social organizations, such as UNRRA, and generally with success. Propaganda, however, is not quite the same thing as education. To educate a man it is necessary to do more than jolt him out of his daydreams. The brief exhortation or appeal needs to be supplemented by a patient campaign of

enlightenment, carried on not by journalists or comic artists or publicity experts but by such people as health officers, sanitary inspectors, health visitors, school nurses and teachers, and members of the medical profession, all of whom in their quiet ways can help to transform into a settled habit the passing reaction of the public to the propaganda they have heard and seen

Instruction in matters of health, which wartime experience showed to be an essential service, has yet many fields in which to begin its work or to consolidate its position. Three directions may be mentioned in which it has not yet been overworked. Two of them were referred to by Sir Andrew Davidson, Chief Medical Officer of the Department of Health for Scotland, in an address at the opening of the Summer School of the Scottish Council for Health Education. In the first place, more attention might be given to health instruction during that critical period in the life of a youth when he leaves school and enters employment. This change of surroundings and occupation is often accompanied by decline in health and minor sickness, partly no doubt the result of maladjustment. Something might be done to impress on parents the need for special home care at such a period, on employers the importance of a proper working environment, and on the young people themselves certain health rules and precautions. Another direction in which more might be done is the education of older people, even of old people, for the ageing process has its risks and stresses, and counsel is needed as much at one end of life as at the other. There is one other field in which the facilities commanded by health education might be used, and that is to prepare people for the doctor even at a time when there is no sign that they will need him. The doctor undergoes a long training to enable him presently to meet his patient, but nothing is done to prepare the potential patient to meet his doctor. A little instruction from this point of view might help to create the "good patient", it might break down in advance the reserve which during illness often delays the doctor's efforts and the patient's recovery. It might also do something to dispel preconceived ideas and prejudices in the patient's mind.

METHYLENE BLUE AND THE CHEMOTHERAPY OF SCRUB TYPHUS

Methylene blue has long been known to have a slight chemotherapeutic action against such widely differing organisms as trypanosomes, malarial plasmodia, the gonococcus, and diphtheria bacillus. Methylene blue, in fact, was the starting-point from which plasmoquine or, as it was known during the war, pamaquine, was evolved. In 1936 Otto and Schofer¹ found that methylene blue had some action against murine typhus infections in mice, a finding later confirmed by Kikuth and Schilling² in experimental murine typhus in guinea-pigs. The action of methylene blue has been further studied by McLimans and Grant³ in infections due to the rickettsia of scrub typhus, *Rickettsia tsutsugamushi* (= *R. orientalis*). When methylene blue was added to the diet to the extent of 0.2%, ninety-six hours after inoculation, it reduced the mortality to 30-40%, as contrasted with a 90-100% mortality in the untreated

controls. If, in addition, the mice were exposed to an atmosphere containing 50% of oxygen the mortality of the treated mice was reduced to from 20-30%.

In order to compare the curative effects of *p*-aminobenzoic acid and methylene blue with oxygen, mice were inoculated intraperitoneally with *R. tsutsugamushi* and after varying intervals therapy was instituted, the methylene blue and *p*-aminobenzoic acid being both added to the diet to the extent of 0.4%. While the methylene blue with oxygen inhalation invariably saved a higher percentage of mice than *p*-aminobenzoic acid, it is noteworthy that when therapy was delayed for more than 120 hours after infection *p*-aminobenzoic acid was quite ineffective but methylene blue and oxygen still had an appreciable effect. Even when the concentration of *p*-aminobenzoic acid in the diet was increased to 1% it was always less efficient than methylene blue and oxygen.

In the treatment of scrub typhus in man methylene blue alone has so far proved ineffectual (Steele *et al.*⁴), but in view of the well-established function of methylene blue as a catalyst of numerous enzyme reactions and as a carrier of oxygen, studies of the action of this drug in other rickettsial and virus infections may well be of considerable interest. It will be remembered that more than twenty years ago Gordon⁵ demonstrated that vaccinia and variola viruses are very readily inactivated by an oxidizing agent such as potassium permanganate, a clue to the chemotherapy of virus diseases which up till now has not been pursued.

REITER'S SYNDROME

The syndrome consisting of polyarthritis, urethritis, and conjunctivitis, originally described by Reiter in 1916, is perhaps not yet entitled to be known as Reiter's disease since its aetiology remains obscure, and it is consequently not known to be a single entity. Cases have recently been reported in the *Journal* by Jackson,⁶ Wrigley,⁷ and Baxter⁸ while several correspondents^{9, 11} have discussed its possible relationship to bacillary dysentery. The association between these two conditions seems to be far from constant and the evidence as a whole does not support the belief that Reiter's syndrome has any consistent connexion with intestinal disease. The resemblance to gonorrhoea is striking only in the distribution of the lesions, all tests for gonococcal infection give negative results, and neither sulphonamides nor penicillin are curative. The disease runs a long febrile course, its different manifestations often appearing successively and the arthritis migrating from one joint to another. It is apparently confined to young adult males and is not considered to be venereal in origin. No explanation of this age and sex distribution can be offered.

In the absence of any demonstrable causative bacterium it has been supposed that the disease is due to a virus, and Harkness¹² claims to have demonstrated inclusion bodies in material from the urethra and conjunctiva. Also incriminated are the so-called 'pleuropneumonia-like' organisms, which have so long been denied the dignity of proper nomenclature. Although responsible for two specific animal diseases—bovine pleuropneumonia and contagious agalactia of sheep—these organisms have not been fully identified as the cause of any human disease, though they

exist in the human body. Their extreme pleomorphism and the special techniques required for their study are obstacles to ready recognition, and perhaps much remains to be discovered about their activities in relation to human pathology. It may be recalled in passing that Swift and Brown¹³ claimed to have cultivated these organisms from joint fluid in cases of rheumatic fever. The part they play in disease of the genital tract is uncertain, their frequent presence in cases of urethritis, gonococcal and other, is lessened in significance by their demonstration in the same situation in normal subjects. A contribution to the study of Reiter's syndrome from this point of view by R. R. Willcox, G. M. Findlay, and A. Henderson-Begg will be found at page 483 of this issue. These authors point not only to the somewhat equivocal evidence based on the examination of human material but to the existence of conjunctivitis and arthritis due to pleuropneumonia-like organisms in animals, including rats and mice, as encouraging the further search for such organisms in cases of Reiter's syndrome. They investigated two cases, inoculating mice with blood and joint fluid, with no further result than the production of a non-transmissible arthritis in a single mouse. Their other line of argument is therapeutic: pleuropneumonia-like organisms are sensitive to gold salts, and these two patients were accordingly treated with myocrisin. This appears to have had a very satisfactory effect, the lesions resolving and the sedimentation rate falling steadily. As the authors rightly indicate, this is no proof of a particular aetiology, since many drugs are active against more than one type of micro-organism. On the other hand, it is the result to be expected in accordance with their hypothesis, and in the interests both of further investigation and of successful therapy the effect of gold should certainly be observed in future cases.

ANAESTHESIA BY HYPNOSIS

Last year, just a century after James Esdaile's¹⁴ successful use of mesmerism for surgical operations at the Hooghly Hospital, Calcutta, the exigencies of a prisoner-of-war hospital near Singapore led Sampimon and Woodruff¹⁵ to try hypnosis as a substitute for more orthodox methods of anaesthesia. Supplies of anaesthetic agents were meagre and uncertain, and many casualties were likely to occur. It was decided to attempt the use of hypnosis in selected dental and surgical cases. Hypnosis was induced with the patient lying supine on a table. The method employed was that of convergence fatigue, the patient being instructed to fix his gaze upon the point of a pencil held at the minimum distance of distinct vision. This method originated with the physician James Braid during the early eighteenth-forties, and it was he who named it hypnotism. His main purpose was to get patients into a suggestive state for the treatment of a variety of ailments—for example, rheumatic conditions and neuralgia—but on a few occasions Braid painlessly extracted teeth from entranced patients.

Among Sampimon and Woodruff's patients there were 23 for dental extractions. Other successful cases included the removal of nails and the incision and drainage of suppurating wounds. It was found easier to induce hypnosis in reasonably intelligent patients than in mental defectives, but beyond this they could discern no general principles which would indicate in advance whether a given patient was likely to prove a good subject. An aspect of hypnosis stressed by these authors was the importance of verbal assurance by the hypnotist during the course of the hyp-

notic sleep that neither operative nor post-operative pain would be felt, nor would the operation be remembered. They claim that in two cases in which the attempt to induce hypnosis failed the mere suggestion of anaesthesia enabled the operation to be performed. In another case of failure the subject was subsequently found to be deaf and so had not heard many of the suggestions made to him. When post-operative pain occurred the authors traced it to the omission of appropriate suggestions or to waking the patient too soon (that is, less than ten minutes) after the final suggestions had been made.
